SPF Water Engineering ACZ Project ID: ***L41754***

ACZ ID	WORKNUM	PARAMETER	METHOD	QUAL	DESCRIPTION
L41754-01	WG439029	Antimony, total	M200.8 ICP-MS	M3	The spike recovery value is unusable since the analyte concentration in the sample is disproportionate to the spike level. The recovery of the associated control sample (LCS or LFB) was acceptable.
	WG438849	Beryllium, dissolved	M200.8 ICP-MS	VC	CCV recovery was above the acceptance limits. Target analyte was not detected in the sample [< MDL].
	WG438878	Cyanide, total	M335.4 - Colorimetric w/ distillation	RA	Relative Percent Difference (RPD) was not used for data validation because the concentration of the duplicated sample is too low for accurate evaluation (< 10x MDL).
	WG438693	Cyanide, WAD	SM4500-CN I,E-Colorimetric w/ distillation	RA	Relative Percent Difference (RPD) was not used for data validation because the concentration of the duplicated sample is too low for accurate evaluation (< 10x MDL).
	WG438601	Fluoride	M300.0 - Ion Chromatography	DC	Sample required dilution. Non-target analyte exceeded calibration range.
			M300.0 - Ion Chromatography	RA	Relative Percent Difference (RPD) was not used for data validation because the concentration of the duplicated sample is too low for accurate evaluation (< 10x MDL).
	WG438769	Nitrogen, ammonia	M350.1 Auto Salicylate w/gas diffusion	RA	Relative Percent Difference (RPD) was not used for data validation because the concentration of the duplicated sample is too low for accurate evaluation (< 10x MDL).
	WG438796	Phosphorus, total	M365.1 - Auto Ascorbic Acid (digest)	RA	Relative Percent Difference (RPD) was not used for data validation because the concentration of the duplicated sample is too low for accurate evaluation (< 10x MDL).
	WG438313	Residue, Non-Filterable (TSS) @105C	SM2540D	RA	Relative Percent Difference (RPD) was not used for data validation because the concentration of the duplicated sample is too low for accurate evaluation (< 10x MDL).
	WG439029	Tin, total	M200.8 ICP-MS	M2	Matrix spike recovery was low, the recovery of the associated control sample (LCS or LFB) was acceptable.

Sample Receipt

SPF Water Engineering
Calico Monitoring Well Sampling

ACZ Project ID: L41754
Date Received: 12/13/2017 11:59
Received By:
Date Printed: 12/14/2017

Receipt Verification

	YES	NO	NA
1) Is a foreign soil permit included for applicable samples?			X
2) Is the Chain of Custody form or other directive shipping papers present?	X		
3) Does this project require special handling procedures such as CLP protocol?		X	
4) Are any samples NRC licensable material?			X
5) If samples are received past hold time, proceed with requested short hold time analyses?	X		
6) Is the Chain of Custody form complete and accurate?	X		
7) Were any changes made to the Chain of Custody form prior to ACZ receiving the samples?		X	

Samples/Containers

	YES	NO	NA
8) Are all containers intact and with no leaks?	X		
9) Are all labels on containers and are they intact and legible?	X		
10) Do the sample labels and Chain of Custody form match for Sample ID, Date, and Time?	X		
11) For preserved bottle types, was the pH checked and within limits? [1]	X		
12) Is there sufficient sample volume to perform all requested work?	X		
13) Is the custody seal intact on all containers?			X
14) Are samples that require zero headspace acceptable?			X
15) Are all sample containers appropriate for analytical requirements?	X		
16) Is there an Hg-1631 trip blank present?	X		
17) Is there a VOA trip blank present?			X
18) Were all samples received within hold time?	X		

NA indicates Not Applicable

Chain of Custody Related Remarks

Client Contact Remarks

Shipping Containers

Cooler Id	Temp(°C)	Temp Criteria(°C)	Rad(µR/Hr)	Custody Seal Intact?
NA27494	3.9	<=6.0	15	Yes

Was ice present in the shipment container(s)?

Yes - Wet ice was present in the shipment container(s).

Client must contact an ACZ Project Manager if analysis should not proceed for samples received outside of their thermal preservation acceptance criteria.

If sample(s) received past holding time (HT), or if insufficient HT remains to complete analysis before expiration, shall ACZ proceed with requested short HT analyses? YES [X] NO [ ]

If "NO" then ACZ will contact client for further instruction. If neither "YES" nor "NO" is indicated, ACZ will proceed with the requested analyses, even if HT is expired, and data will be qualified

Are samples for SDWA Compliance Monitoring? Yes [ ] No [X]

If yes, please include state forms. Results will be reported to PQL for Colorado.

Sampler's Name: Kurt Newbry Sampler's Site Information State ID Zip code 83706 Time Zone MTN

*Sampler's Signature: _____ *I attest to the authenticity and validity of this sample. I understand that intentionally mislabeling the time/date/location or tampering with the sample in anyway, is considered fraud and punishable by State Law.

Analytical Report

January 05, 2018

Report to:
Jason Thompson
SPF Water Engineering
300 E. Mallard Drive, Suite 350

Boise, ID 83706

cc: Kurt Newbry

Bill to:
Jason Thompson
SPF Water Engineering
300 E Mallard Drive
Suite 350
Boise, ID 83706

Project ID: Calico Monitoring Well Samplin
ACZ Project ID: L41826

Jason Thompson:

Enclosed are the analytical results for sample(s) submitted to ACZ Laboratories, Inc. (ACZ) on December 16, 2017. This project has been assigned to ACZ's project number, L41826. Please reference this number in all future inquiries.

All analyses were performed according to ACZ's Quality Assurance Plan. The enclosed results relate only to the samples received under L41826. Each section of this report has been reviewed and approved by the appropriate Laboratory Supervisor, or a qualified substitute.

Except as noted, the test results for the methods and parameters listed on ACZ's current NELAC certificate letter (#ACZ) meet all requirements of NELAC.

This report shall be used or copied only in its entirety. ACZ is not responsible for the consequences arising from the use of a partial report.

All samples and sub-samples associated with this project will be disposed of after February 04, 2018. If the samples are determined to be hazardous, additional charges apply for disposal (typically $11/sample). If you would like the samples to be held longer than ACZ's stated policy or to be returned, please contact your Project Manager or Customer Service Representative for further details and associated costs. ACZ retains analytical raw data reports for ten years.

If you have any questions or other needs, please contact your Project Manager.

Max Janicek has reviewed and approved this report.

Report Header Explanations

Batch	A distinct set of samples analyzed at a specific time
Found	Value of the QC Type of interest
Limit	Upper limit for RPD, in %.
Lower	Lower Recovery Limit, in % (except for LCSS, mg/Kg)
MDL	Method Detection Limit. Same as Minimum Reporting Limit unless omitted or equal to the PQL (see comment #5). Allows for instrument and annual fluctuations.
PCN/SCN	A number assigned to reagents/standards to trace to the manufacturer's certificate of analysis
PQL	Practical Quantitation Limit. Synonymous with the EPA term "minimum level".
QC	True Value of the Control Sample or the amount added to the Spike
Rec	Recovered amount of the true value or spike added, in % (except for LCSS, mg/Kg)
RPD	Relative Percent Difference, calculation used for Duplicate QC Types
Upper	Upper Recovery Limit, in % (except for LCSS, mg/Kg)
Sample	Value of the Sample of interest

QC Sample Types

AS	Analytical Spike (Post Digestion)	*LCSWD*	Laboratory Control Sample - Water Duplicate
ASD	Analytical Spike (Post Digestion) Duplicate	*LFB*	Laboratory Fortified Blank
CCB	Continuing Calibration Blank	*LFM*	Laboratory Fortified Matrix
CCV	Continuing Calibration Verification standard	*LFMD*	Laboratory Fortified Matrix Duplicate
DUP	Sample Duplicate	*LRB*	Laboratory Reagent Blank
ICB	Initial Calibration Blank	*MS*	Matrix Spike
ICV	Initial Calibration Verification standard	*MSD*	Matrix Spike Duplicate
ICSAB	Inter-element Correction Standard - A plus B solutions	*PBS*	Prep Blank - Soil
LCSS	Laboratory Control Sample - Soil	*PBW*	Prep Blank - Water
LCSSD	Laboratory Control Sample - Soil Duplicate	*PQV*	Practical Quantitation Verification standard
LCSW	Laboratory Control Sample - Water	*SDL*	Serial Dilution

QC Sample Type Explanations

Blanks	Verifies that there is no or minimal contamination in the prep method or calibration procedure.
Control Samples	Verifies the accuracy of the method, including the prep procedure.
Duplicates	Verifies the precision of the instrument and/or method.
Spikes/Fortified Matrix	Determines sample matrix interferences, if any.
Standard	Verifies the validity of the calibration.

ACZ Qualifiers (Qual)

B	Analyte concentration detected at a value between MDL and PQL. The associated value is an estimated quantity.
H	Analysis exceeded method hold time. pH is a field test with an immediate hold time.
L	Target analyte response was below the laboratory defined negative threshold.
U	The material was analyzed for, but was not detected above the level of the associated value. The associated value is either the sample quantitation limit or the sample detection limit.

Method References

(3)	EPA 600/R-94-111. Methods for the Determination of Metals in Environmental Samples - Supplement I, May 1994.
(4)	EPA SW-846. Test Methods for Evaluating Solid Waste.
(5)	Standard Methods for the Examination of Water and Wastewater.

Comments

(1)	QC results calculated from raw data. Results may vary slightly if the rounded values are used in the calculations.
(2)	Soil, Sludge, and Plant matrices for Inorganic analyses are reported on a dry weight basis.
(3)	Animal matrices for Inorganic analyses are reported on an "as received" basis.
(4)	An asterisk in the "XQ" column indicates there is an extended qualifier and/or certification qualifier associated with the result.
(5)	If the MDL equals the PQL or the MDL column is omitted, the PQL is the reporting limit.

	YES	NO	NA
1) Is a foreign soil permit included for applicable samples?			X
2) Is the Chain of Custody form or other directive shipping papers present?	X		
3) Does this project require special handling procedures such as CLP protocol?		X	
4) Are any samples NRC licensable material?			X
5) If samples are received past hold time, proceed with requested short hold time analyses?	X		
6) Is the Chain of Custody form complete and accurate?	X		
7) Were any changes made to the Chain of Custody form prior to ACZ receiving the samples?	X		

A change was made in the Report to Name. Copy of Report to Email. Sample ID Line 1. Relinquished By section prior to ACZ custody.

Samples/Containers

	YES	NO	NA
8) Are all containers intact and with no leaks?	X		
9) Are all labels on containers and are they intact and legible?	X		
10) Do the sample labels and Chain of Custody form match for Sample ID, Date, and Time?	X		
11) For preserved bottle types, was the pH checked and within limits? [1]	X		
12) Is there sufficient sample volume to perform all requested work?	X		
13) Is the custody seal intact on all containers?			X
14) Are samples that require zero headspace acceptable?			X
15) Are all sample containers appropriate for analytical requirements?	X		
16) Is there an Hg-1631 trip blank present?	X		
17) Is there a VOA trip blank present?			X
18) Were all samples received within hold time?	X		

NA indicates Not Applicable

Jason Thompson:

Enclosed are the analytical results for sample(s) submitted to ACZ Laboratories, Inc. (ACZ) on July 26, 2018. This project has been assigned to ACZ's project number, L45855. Please reference this number in all future inquiries.

All analyses were performed according to ACZ's Quality Assurance Plan. The enclosed results relate only to the samples received under L45855. Each section of this report has been reviewed and approved by the appropriate Laboratory Supervisor, or a qualified substitute.

Except as noted, the test results for the methods and parameters listed on ACZ's current NELAC certificate letter (#ACZ) meet all requirements of NELAC.

This report shall be used or copied only in its entirety. ACZ is not responsible for the consequences arising from the use of a partial report.

All samples and sub-samples associated with this project will be disposed of after September 12, 2018. If the samples are determined to be hazardous, additional charges apply for disposal (typically $11/sample). If you would like the samples to be held longer than ACZ's stated policy or to be returned, please contact your Project Manager or Customer Service Representative for further details and associated costs. ACZ retains analytical raw data reports for ten years.

If you have any questions or other needs, please contact your Project Manager.

Sue Webber has reviewed and approved this report.

SPF Water Engineering

August 13, 2018

Project ID:
ACZ Project ID: L45855

Sample Receipt

ACZ Laboratories, Inc. (ACZ) received 2 groundwater samples from SPF Water Engineering on July 26, 2018. The samples were received in good condition. Upon receipt, the sample custodian removed the samples from the cooler, inspected the contents, and logged the samples into ACZ's computerized Laboratory Information Management System (LIMS). The samples were assigned ACZ LIMS project number L45855. The custodian verified the sample information entered into the computer against the chain of custody (COC) forms and sample bottle labels.

Holding Times

All analyses were performed within EPA recommended holding times.

Sample Analysis

These samples were analyzed for inorganic parameters. The individual methods are referenced on both, the ACZ invoice and the analytical reports. The following required further explanation not provided by the Extended Qualifier Report:

1. Tin, dissolved (B1) - Dissolved Tin was flagged with a "B1" in the QC Summary since tin was detected in the ICB over the limit at 0.00046 mg/L. No further action was taken since dissolved tin was not detected in the sample.

Metals Analysis

Parameter	EPA Method	Dilution	Result	Qual	XQ	Units	MDL	PQL	Date	Analyst
Mercury, dissolved	M1631, Atomic Fluorescence	1		U		ng/L	0.2	0.5	08/10/18 9:48	mfm
Mercury, total	M1631, Atomic Fluorescence	1		U		ng/L	0.2	0.5	08/06/18 11:52	mfm

Report Header Explanations

Batch	A distinct set of samples analyzed at a specific time
Found	Value of the QC Type of interest
Limit	Upper limit for RPD, in %.
Lower	Lower Recovery Limit, in % (except for LCSS, mg/Kg)
MDL	Method Detection Limit. Same as Minimum Reporting Limit unless omitted or equal to the PQL (see comment #5). Allows for instrument and annual fluctuations.
PCN/SCN	A number assigned to reagents/standards to trace to the manufacturer's certificate of analysis
PQL	Practical Quantitation Limit. Synonymous with the EPA term "minimum level".
QC	True Value of the Control Sample or the amount added to the Spike
Rec	Recovered amount of the true value or spike added, in % (except for LCSS, mg/Kg)
RPD	Relative Percent Difference, calculation used for Duplicate QC Types
Upper	Upper Recovery Limit, in % (except for LCSS, mg/Kg)
Sample	Value of the Sample of interest

QC Sample Types

AS	Analytical Spike (Post Digestion)	*LCSWD*	Laboratory Control Sample - Water Duplicate
ASD	Analytical Spike (Post Digestion) Duplicate	*LFB*	Laboratory Fortified Blank
CCB	Continuing Calibration Blank	*LFM*	Laboratory Fortified Matrix
CCV	Continuing Calibration Verification standard	*LFMD*	Laboratory Fortified Matrix Duplicate
DUP	Sample Duplicate	*LRB*	Laboratory Reagent Blank
ICB	Initial Calibration Blank	*MS*	Matrix Spike
ICV	Initial Calibration Verification standard	*MSD*	Matrix Spike Duplicate
ICSAB	Inter-element Correction Standard - A plus B solutions	*PBS*	Prep Blank - Soil
LCSS	Laboratory Control Sample - Soil	*PBW*	Prep Blank - Water
LCSSD	Laboratory Control Sample - Soil Duplicate	*PQV*	Practical Quantitation Verification standard
LCSW	Laboratory Control Sample - Water	*SDL*	Serial Dilution

QC Sample Type Explanations

Blanks	Verifies that there is no or minimal contamination in the prep method or calibration procedure.
Control Samples	Verifies the accuracy of the method, including the prep procedure.
Duplicates	Verifies the precision of the instrument and/or method.
Spikes/Fortified Matrix	Determines sample matrix interferences, if any.
Standard	Verifies the validity of the calibration.

ACZ Qualifiers (Qual)

B	Analyte concentration detected at a value between MDL and PQL. The associated value is an estimated quantity.
H	Analysis exceeded method hold time. pH is a field test with an immediate hold time.
L	Target analyte response was below the laboratory defined negative threshold.
U	The material was analyzed for, but was not detected above the level of the associated value. The associated value is either the sample quantitation limit or the sample detection limit.

Method References

(1)	EPA 600/4-83-020. Methods for Chemical Analysis of Water and Wastes, March 1983.
(2)	EPA 600/R-93-100. Methods for the Determination of Inorganic Substances in Environmental Samples, August 1993.
(3)	EPA 600/R-94-111. Methods for the Determination of Metals in Environmental Samples - Supplement I, May 1994.
(4)	EPA SW-846. Test Methods for Evaluating Solid Waste.
(5)	Standard Methods for the Examination of Water and Wastewater.

Comments

(1)	QC results calculated from raw data. Results may vary slightly if the rounded values are used in the calculations.
(2)	Soil, Sludge, and Plant matrices for Inorganic analyses are reported on a dry weight basis.
(3)	Animal matrices for Inorganic analyses are reported on an "as received" basis.
(4)	An asterisk in the "XQ" column indicates there is an extended qualifier and/or certification qualifier associated with the result.
(5)	If the MDL equals the PQL or the MDL column is omitted, the PQL is the reporting limit.

For a complete list of ACZ's Extended Qualifiers, please click: http://www.acz.com/public/extquallist.pdf

ACZ Project ID: ***L45855***

ACZ ID	WORKNUM	PARAMETER	METHOD	QUAL	DESCRIPTION
L45855-01	WG452953	Chloride	M300.0 - Ion Chromatography	RA	Relative Percent Difference (RPD) was not used for data validation because the concentration of the duplicated sample is too low for accurate evaluation (< 10x MDL).
	WG453783	Cyanide, total	M335.4 - Colorimetric w/ distillation	M2	Matrix spike recovery was low, the recovery of the associated control sample (LCS or LFB) was acceptable.
			M335.4 - Colorimetric w/ distillation	RA	Relative Percent Difference (RPD) was not used for data validation because the concentration of the duplicated sample is too low for accurate evaluation (< 10x MDL).
	WG452722	Cyanide, WAD	SM4500-CN I,E-Colorimetric w/ distillation	RA	Relative Percent Difference (RPD) was not used for data validation because the concentration of the duplicated sample is too low for accurate evaluation (< 10x MDL).
	WG452953	Fluoride	M300.0 - Ion Chromatography	M1	Matrix spike recovery was high, the recovery of the associated control sample (LCS or LFB) was acceptable.
			M300.0 - Ion Chromatography	RA	Relative Percent Difference (RPD) was not used for data validation because the concentration of the duplicated sample is too low for accurate evaluation (< 10x MDL).
	WG453161	Iron, total	M200.7 ICP	M3	The spike recovery value is unusable since the analyte concentration in the sample is disproportionate to the spike level. The recovery of the associated control sample (LCS or LFB) was acceptable.
	WG453228	Nitrate/Nitrite as N	M353.2 - H2SO4 preserved	RA	Relative Percent Difference (RPD) was not used for data validation because the concentration of the duplicated sample is too low for accurate evaluation (< 10x MDL).
	WG453275	Nitrogen, ammonia	M350.1 Auto Salicylate w/gas diffusion	RA	Relative Percent Difference (RPD) was not used for data validation because the concentration of the duplicated sample is too low for accurate evaluation (< 10x MDL).
	WG452914	Phosphorus, total	M365.1 - Auto Ascorbic Acid (digest)	M2	Matrix spike recovery was low, the recovery of the associated control sample (LCS or LFB) was acceptable.
			M365.1 - Auto Ascorbic Acid (digest)	RA	Relative Percent Difference (RPD) was not used for data validation because the concentration of the duplicated sample is too low for accurate evaluation (< 10x MDL).
	WG452695	Residue, Non-Filterable (TSS) @105C	SM2540D	RA	Relative Percent Difference (RPD) was not used for data validation because the concentration of the duplicated sample is too low for accurate evaluation (< 10x MDL).
	WG453574	Tin, dissolved	M200.8 ICP-MS	BE	Target analyte in continuing calibration blank (CCB) at or above the acceptance criteria. Target analyte was not detected in the sample [< MDL].
	WG453420	Tin, total	M200.8 ICP-MS	M2	Matrix spike recovery was low, the recovery of the associated control sample (LCS or LFB) was acceptable.

2773 Downhill Drive Steamboat Springs, CO 80487 (800) 334-5493

Sample Receipt

SPF Water Engineering

ACZ Project ID: L45855
Date Received: 07/26/2018 11:46
Received By:
Date Printed: 7/27/2018

Receipt Verification

	YES	NO	NA
1) Is a foreign soil permit included for applicable samples?			X
2) Is the Chain of Custody form or other directive shipping papers present?	X		
3) Does this project require special handling procedures such as CLP protocol?		X	
4) Are any samples NRC licensable material?			X
5) If samples are received past hold time, proceed with requested short hold time analyses?	X		
6) Is the Chain of Custody form complete and accurate?	X		
7) Were any changes made to the Chain of Custody form prior to ACZ receiving the samples?	X		

A change was made in the Copy of Report to: E-Mail. Sample ID: Matrix section prior to ACZ custody.

Samples/Containers

	YES	NO	NA
8) Are all containers intact and with no leaks?	X		
9) Are all labels on containers and are they intact and legible?	X		
10) Do the sample labels and Chain of Custody form match for Sample ID, Date, and Time?	X		
11) For preserved bottle types, was the pH checked and within limits? [1]	X		
12) Is there sufficient sample volume to perform all requested work?	X		
13) Is the custody seal intact on all containers?			X
14) Are samples that require zero headspace acceptable?			X
15) Are all sample containers appropriate for analytical requirements?	X		
16) Is there an Hg-1631 trip blank present?	X		
17) Is there a VOA trip blank present?			X
18) Were all samples received within hold time?	X		

NA indicates Not Applicable

Chain of Custody Related Remarks

Client Contact Remarks

Shipping Containers

Cooler Id	Temp(°C)	Temp Criteria(°C)	Rad(µR/Hr)	Custody Seal Intact?
5059	5.7	<=6.0	17	Yes

Was ice present in the shipment container(s)?

Yes - Wet ice was present in the shipment container(s).

Client must contact an ACZ Project Manager if analysis should not proceed for samples received outside of their thermal preservation acceptance criteria.

Quarterly Analysis of Groundwater and Springs

Client is responsible for necessary field filtering

PACK	Qty	Type	Size	Filter/Raw/Preserve	Instructions
	1	GREEN PC	125 ML	Green pre-cleaned Filtered/Nitiric	Metals (dissolved including ICPMS) - Filter sample with .45 micron filter. Do not overfill as there is Nitric Acid in the bottle.
	1	HG-1631	250 ML	Mercury 1631	Mercury by 1631 - See method specific sampling instructions.
	1	HG-1631 D	250 ML	Mercury 1631 Dissolved	Mercury (dissolved) by 1631 - See method specific sampling instructions.
	1	PURPLE	250 ML	Raw/NaOH	Cyanide - Do not overfill as there is Sodium Hydroxide in the bottle.
	1	RAW	500 ML	Raw	Wet Chemistry (analyses that do not require preservative or filtration) - Completely fill container.
	1	RED PC	250 ML	Red pre-cleaned Raw/Nitric	Metals (total including ICPMS) - Do not overfill as there is Nitric Acid in the bottle.
	1	WHITE	250 ML	Filtered	Wet chemistry (dissolved) - Filter sample with .45 micron filter. Completely fill container.
	1	YELLOW	250 ML	Raw/Sulfuric	For total wet chemistry analyses. Do not overfill as there is Sulfuric Acid in the bottle.

Suite 350
Boise, ID 83706

Project ID:
ACZ Project ID: L48680

Jason Thompson:

Enclosed are the analytical results for sample(s) submitted to ACZ Laboratories, Inc. (ACZ) on December 07, 2018. This project has been assigned to ACZ's project number, L48680. Please reference this number in all future inquiries.

All analyses were performed according to ACZ's Quality Assurance Plan. The enclosed results relate only to the samples received under L48680. Each section of this report has been reviewed and approved by the appropriate Laboratory Supervisor, or a qualified substitute.

Except as noted, the test results for the methods and parameters listed on ACZ's current NELAC certificate letter (#ACZ) meet all requirements of NELAC.

This report shall be used or copied only in its entirety. ACZ is not responsible for the consequences arising from the use of a partial report.

All samples and sub-samples associated with this project will be disposed of after January 20, 2019. If the samples are determined to be hazardous, additional charges apply for disposal (typically $11/sample). If you would like the samples to be held longer than ACZ's stated policy or to be returned, please contact your Project Manager or Customer Service Representative for further details and associated costs. ACZ retains analytical raw data reports for ten years.

If you have any questions or other needs, please contact your Project Manager.

Max Janicek has reviewed and approved this report.

Report Header Explanations

Batch	A distinct set of samples analyzed at a specific time
Found	Value of the QC Type of interest
Limit	Upper limit for RPD, in %.
Lower	Lower Recovery Limit, in % (except for LCSS, mg/Kg)
MDL	Method Detection Limit. Same as Minimum Reporting Limit unless omitted or equal to the PQL (see comment #5). Allows for instrument and annual fluctuations.
PCN/SCN	A number assigned to reagents/standards to trace to the manufacturer's certificate of analysis
PQL	Practical Quantitation Limit. Synonymous with the EPA term "minimum level".
QC	True Value of the Control Sample or the amount added to the Spike
Rec	Recovered amount of the true value or spike added, in % (except for LCSS, mg/Kg)
RPD	Relative Percent Difference, calculation used for Duplicate QC Types
Upper	Upper Recovery Limit, in % (except for LCSS, mg/Kg)
Sample	Value of the Sample of interest

QC Sample Types

AS	Analytical Spike (Post Digestion)	*LCSWD*	Laboratory Control Sample - Water Duplicate
ASD	Analytical Spike (Post Digestion) Duplicate	*LFB*	Laboratory Fortified Blank
CCB	Continuing Calibration Blank	*LFM*	Laboratory Fortified Matrix
CCV	Continuing Calibration Verification standard	*LFMD*	Laboratory Fortified Matrix Duplicate
DUP	Sample Duplicate	*LRB*	Laboratory Reagent Blank
ICB	Initial Calibration Blank	*MS*	Matrix Spike
ICV	Initial Calibration Verification standard	*MSD*	Matrix Spike Duplicate
ICSAB	Inter-element Correction Standard - A plus B solutions	*PBS*	Prep Blank - Soil
LCSS	Laboratory Control Sample - Soil	*PBW*	Prep Blank - Water
LCSSD	Laboratory Control Sample - Soil Duplicate	*PQV*	Practical Quantitation Verification standard
LCSW	Laboratory Control Sample - Water	*SDL*	Serial Dilution

QC Sample Type Explanations

Blanks	Verifies that there is no or minimal contamination in the prep method or calibration procedure.
Control Samples	Verifies the accuracy of the method, including the prep procedure.
Duplicates	Verifies the precision of the instrument and/or method.
Spikes/Fortified Matrix	Determines sample matrix interferences, if any.
Standard	Verifies the validity of the calibration.

ACZ Qualifiers (Qual)

B	Analyte concentration detected at a value between MDL and PQL. The associated value is an estimated quantity.
H	Analysis exceeded method hold time. pH is a field test with an immediate hold time.
L	Target analyte response was below the laboratory defined negative threshold.
U	The material was analyzed for, but was not detected above the level of the associated value. The associated value is either the sample quantitation limit or the sample detection limit.

Method References

(5)	Standard Methods for the Examination of Water and Wastewater.

Comments

(1)	QC results calculated from raw data. Results may vary slightly if the rounded values are used in the calculations.
(2)	Soil, Sludge, and Plant matrices for Inorganic analyses are reported on a dry weight basis.
(3)	Animal matrices for Inorganic analyses are reported on an "as received" basis.
(4)	An asterisk in the "XQ" column indicates there is an extended qualifier and/or certification qualifier associated with the result.
(5)	If the MDL equals the PQL or the MDL column is omitted, the PQL is the reporting limit.

For a complete list of ACZ's Extended Qualifiers, please click: http://www.acz.com/public/extquallist.pdf

Sample Receipt

SPF Water Engineering

ACZ Project ID: L48680
Date Received: 12/07/2018 11:55
Received By:
Date Printed: 12/7/2018

Receipt Verification

	YES	NO	NA
1) Is a foreign soil permit included for applicable samples?			X
2) Is the Chain of Custody form or other directive shipping papers present?	X		
3) Does this project require special handling procedures such as CLP protocol?		X	
4) Are any samples NRC licensable material?			X
5) If samples are received past hold time, proceed with requested short hold time analyses?	X		
6) Is the Chain of Custody form complete and accurate?	X		
7) Were any changes made to the Chain of Custody form prior to ACZ receiving the samples?	X		

A change was made in the Remarks section prior to ACZ custody.

Samples/Containers

	YES	NO	NA
8) Are all containers intact and with no leaks?	X		
9) Are all labels on containers and are they intact and legible?	X		
10) Do the sample labels and Chain of Custody form match for Sample ID, Date, and Time?	X		
11) For preserved bottle types, was the pH checked and within limits? [1]	X		
12) Is there sufficient sample volume to perform all requested work?	X		
13) Is the custody seal intact on all containers?			X
14) Are samples that require zero headspace acceptable?			X
15) Are all sample containers appropriate for analytical requirements?	X		
16) Is there an Hg-1631 trip blank present?	X		
17) Is there a VOA trip blank present?			X
18) Were all samples received within hold time?		X	

Some parameters were received past hold time.

NA indicates Not Applicable

If sample(s) received past holding time (HT), or if insufficient HT remains to complete analysis before expiration, shall ACZ proceed with requested short HT analyses? YES ☐ NO ☐

If "NO" then ACZ will contact client for further instruction. If neither "YES" nor "NO" is indicated, ACZ will proceed with the requested analyses, even if HT is expired, and data will be qualified

Are samples for SDWA Compliance Monitoring? Yes ☐ No ☒

If yes, please include state forms. Results will be reported to PQL for Colorado.

Sampler's Name: Sean Albertson **Sampler's Site Information** **State** Idaho **Zip code** 83706 **Time Zone** Mtn.

***Sampler's Signature:** Sean Albert

*I attest to the authenticity and validity of this sample. I understand that intentionally mislabeling the time/date/location or tampering with the sample in anyway, is considered fraud and punishable by State Law.

Quarterly Analysis of Groundwater and Springs

Client is responsible for necessary field filtering

PACK	Qty	Type	Size	Filter/Raw/Preserve	Instructions
	1	GREEN PC	125 ML	Green pre-cleaned Filtered/Nitiric	Metals (dissolved including ICPMS) - Filter sample with .45 micron filter. Do not overfill as there is Nitric Acid in the bottle.
	1	HG-1631	250 ML	Mercury 1631	Mercury by 1631 - See method specific sampling instructions.
	1	HG-1631 D	250 ML	Mercury 1631 Dissolved	Mercury (dissolved) by 1631 - See method specific sampling instructions.
	1	PURPLE	250 ML	Raw/NaOH	Cyanide - Do not overfill as there is Sodium Hydroxide in the bottle.
	1	RAW	500 ML	Raw	Wet Chemistry (analyses that do not require preservative or filtration) - Completely fill container.
	1	RED PC	250 ML	Red pre-cleaned Raw/Nitric	Metals (total including ICPMS) - Do not overfill as there is Nitric Acid in the bottle.
	1	WHITE	250 ML	Filtered	Wet chemistry (dissolved) - Filter sample with .45 micron filter. Completely fill container.
	1	YELLOW	250 ML	Raw/Sulfuric	For total wet chemistry analyses. Do not overfill as there is Sulfuric Acid in the bottle.

Setup charge for ICP, total			$90.00
Setup charge for ICPMS, dissolved			$90.00
Setup charge for ICPMS, total			$90.00
Wet Chemistry			
Alkalinity as CaCO3	SM2320B - Titration	2 mg/L	$12.00
Chloride	M300.0 - Ion Chromatography	0.4 mg/L	$13.00
Conductivity @25C	SM2510B	1 umhos/cm	$8.00
Cyanide, total	M335.4 - Colorimetric w/ distillation	0.003 mg/L	$37.00
Cyanide, WAD	SM4500-CN I,E-Colorimetric w/ distil	0.003 mg/L	$37.00
Fluoride	M300.0 - Ion Chromatography	0.05 mg/L	$13.00
Hardness as CaCO3 (dissolved)	SM2340B - Calculation	Calculation	$0.00
Nitrate/Nitrite as N	M353.2 - H2SO4 preserved	0.02 mg/L	$11.00
Nitrogen, ammonia	M350.1 Auto Salicylate w/gas diffusi	0.05 mg/L	$11.00
pH (lab)	SM4500H+ B	0.1 C	$8.00
Phosphorus, total	M365.1 - Auto Ascorbic Acid (digest)	0.02 mg/L	$23.00
Residue, Filterable (TDS) @180C	SM2540C	10 mg/L	$14.00
Residue, Non-Filterable (TSS) @105C	SM2540D	5 mg/L	$12.00
Sulfate	M300.0 - Ion Chromatography	0.4 mg/L	$13.00
		Cost/Sample:	**$730.00**

ACZ assigns a Project Manager to all of our clients. Your Project Manager is Max Janicek and he will serve as your main point of contact for all bottle orders, report statuses, questions on your data and changes to your account. Max can be reached at maxj@acz.com or 970-879-6590 ext 128.

ACZ Laboratories, Inc.
2773 Downhill Drive Steamboat Springs, CO 80487 (800) 334-5493

Analytical Quote

Quote Number: SPF-2017-GW

CONTRACT DETAILS

Pricing includes shipment of all standard sample containers and related paperwork by UPS Ground Service. Please allow three to five days for delivery when ordering containers. ACZ must be notified prior to receiving samples of all special requests such as electronic data deliverables or special reporting reqirements. The client will be charged for special sample containers or express shipping and additional charges may apply for non-standard requests.

This quotation is valid for six months from the bid date unless specified otherwise in the bid. All bids must be signed and returned to ACZ before the project(s) is received. The authorized signature represents acceptance of the pricing as well as the general terms and conditions of ACZ Laboratories, Inc. which may be downloaded from our web site at http://www.acz.com/PDF/termsconditions.pdf. Please note that MDL's in this quote may possibly increase due to sample matrix or samples with high TDS.

All orders that require shipping of coolers are subject to a minimum charge of $200.00. Local orders without shipping are subject to a minimum charge of $125.00. Samples may incur a $11.00/sample disposal fee for any samples deemed to be hazardous.

[1]Reported values below detection levels were substituted with estimated values for calculation purposes; estimated values were generated by dividing the MDL by √2

[2]If any result (sample or duplicate) is less than the five times the MDL then any difference between the results is generally considered insignificant

[3]RPD of less than 20% between samples is generally considered acceptable (within laboratory testing error)

[4]RPD exceeded 20% and the sample and/or duplicate results were above the RL

Note:
MDL = Minimum Detection Level
RL = Reporting Level (equals 5*MDL)
ND = No Data
RPD = Relative Percent Difference

[1]Reported values below detection levels were substituted with estimated values for calculation purposes; estimated values were generated by dividing the MDL by √2

[2]If any result (sample or duplicate) is less than the five times the MDL then any difference between the results is generally considered insignificant

[3]RPD of less than 20% between samples is generally considered acceptable (within laboratory testing error)

[4]RPD exceeded 20% and the sample and/or duplicate results were above the RL

Note:
MDL = Minimum Detection Level
RL = Reporting Level (equals 5*MDL)
ND = No Data
RPD = Relative Percent Difference

[1]Reported sample values below detection levels, in addition to presumed optimal DI conditions, were substituted with estimated values for calculation purposes; estimated values were generated by dividing the MDL by √2

[2]If any result (sample or duplicate) is less than the five times the MDL then any difference between the results is generally considered insignificant

[3]RPD of less than 20% between samples is generally considered acceptable (within laboratory testing error)

[4]RPD exceeded 20% and the sample and/or duplicate results were above the RL

Note:
MDL = Minimum Detection Level
RL = Reporting Level (equals 5*MDL)
ND = No Data
RPD = Relative Percent Difference
NA = Not Applicable

[1]Reported sample values below detection levels, in addition to presumed optimal DI conditions, were substituted with estimated values for calculation purposes; estimated values were generated by dividing the MDL by √2

[2]If any result (sample or duplicate) is less than the five times the MDL then any difference between the results is generally considered insignificant

[3]RPD of less than 20% between samples is generally considered acceptable (within laboratory testing error)

[4]RPD exceeded 20% and the sample and/or duplicate results were above the RL

Note:
MDL = Minimum Detection Level
RL = Reporting Level (equals 5*MDL)
ND = No Data
RPD = Relative Percent Difference
NA = Not Applicable

[1]Reported sample values below detection levels, in addition to presumed optimal DI conditions, were substituted with estimated values for calculation purposes; estimated values were generated by dividing the MDL by √2

[2]If any result (sample or duplicate) is less than the five times the MDL then any difference between the results is generally considered insignificant

[3]RPD of less than 20% between samples is generally considered acceptable (within laboratory testing error)

[4]RPD exceeded 20% and the sample and/or duplicate results were above the RL

Note:
MDL = Minimum Detection Level
RL = Reporting Level (equals 5*MDL)
ND = No Data
RPD = Relative Percent Difference
NA = Not Applicable

[1]Reported values below detection levels were substituted with estimated values for calculation purposes; estimated values were generated by dividing the MDL by √2

[2]Arithmetic difference between sample and duplicate

[3]RPD compares sample and duplicate, red values are greater than or equal to 20% and the sample and/or duplicate results are greater than 5 times the MDL

Note:
MDL = Minimum Detection Level
RL = Reporting Level (equals 5*MDL)
ND = No Data
RPD = Relative Percent Difference

[1]Reported values below detection levels were substituted with estimated values for calculation purposes; estimated values were generated by dividing the MDL by √2

[2]Arithmetic difference between sample and duplicate

[3]RPD compares sample and duplicate, red values are greater than or equal to 20% and the sample and/or duplicate results are greater than 5 times the MDL

Note:
MDL = Minimum Detection Level
RL = Reporting Level (equals 5*MDL)
ND = No Data
RPD = Relative Percent Difference

[1]Reported values below detection levels were substituted with estimated values for calculation purposes; estimated values were generated by dividing the MDL by √2

[2]Arithmetic difference between sample and duplicate

[3]RPD compares sample and duplicate, red values are greater than or equal to 20% and the sample and/or duplicate results are greater than 5 times the MDL

Note:
MDL = Minimum Detection Level
RL = Reporting Level (equals 5*MDL)
ND = No Data
RPD = Relative Percent Difference

Zinc, total	mg/L	0.0100	0.00707	<0.01	0.00707	0.00	0%

[1]DI water assumed to have values below laboratory minimum detection limit; estimated values were generated by dividing the MDL by √2

[2]Reported values below detection levels were substituted with estimated values for calculation purposes; estimated values were generated by dividing the MDL by √2

[3]Arithmetic difference between estimated DI water value and blank value

[4]RPD compares blank value and estimated DI water value, red values are greater than or equal to 20% and the blank results are greater than 5 times the MDL

Note:
MDL = Minimum Detection Level
RL = Reporting Level (equals 5*MDL)
ND = No Data
RPD = Relative Percent Difference
NA = Not Applicable

Instrument: Dissolved Oxygen Meter
Manufacturer / Model: OxyGuard Handy Polaris 2
Date / Time of Calibration: 3/17/13 12:00
Calibration Method: Auto Cal
Initial DO Saturation Reading: 101% (Should read 100.5%)
Calibration Needed? ____ Yes X No
Calibration Precision: X Field ____ Normal ____ High
Successful Calibration? X Yes ____ No
If No, List Corrective Action:
Signature: S.A.T.

Field Equipment Calibration Record

Instrument: pH Meter
Manufacturer / Model: YSI Ecosense pH100
Date / Time of Calibration: 3-18-13 10:07
Calibration Method: 2 - point
Buffers Used: 7 / 10
Slope Deviation: —
Electrode Efficiency: 100.0
Successful Calibration? ✓ Yes ____ No
If No, List Corrective Action: ____
Signature: [signature]

Instrument: Conductivity Meter
Manufacturer / Model: YSI Ecosense EC300
Date / Time of Calibration: 3-18-13 10:18
Calibration Method: known standard
Cell Constant: 5.00 Default? ✓ Yes ____ No
Temperature Coefficient: 1.91 Default? ✓ Yes ____ No
Temperature Reference: 25 Default? ✓ Yes ____ No
Conductivity Standard: 1413 µS
Conductivity Standard @ 25C: 1413 µS
Successful Calibration? ✓ Yes ____ No
If No, List Corrective Action: ____
Signature: [signature]

Instrument: Dissolved Oxygen Meter
Manufacturer / Model: OxyGuard Handy Polaris 2
Date / Time of Calibration: 3-18-13 10:24
Calibration Method: auto
Initial DO Saturation Reading: 101 (Should read 100.5%)
Calibration Needed? ____ Yes ✓ No
Calibration Precision: ✓ Field ____ Normal ____ High
Successful Calibration? ✓ Yes ____ No
If No, List Corrective Action: ____
Signature: [signature]

Field Equipment Calibration Record

Instrument: pH Meter
Manufacturer / Model: YSI Ecosense pH100
Date / Time of Calibration: 3-25-13 17:05
Calibration Method: 2 - point
Buffers Used: 7.00 / 10.00
Slope Deviation: —
Electrode Efficiency: 97.2
Successful Calibration? ✓ Yes ____ No
If No, List Corrective Action: ____
Signature: [signature]

Instrument: Conductivity Meter
Manufacturer / Model: YSI Ecosense EC300
Date / Time of Calibration: 3-26-13 10:12
Calibration Method: Known Standard
Cell Constant: 5.00 Default? ✓ Yes ____ No
Temperature Coefficient: 1.91 Default? ✓ Yes ____ No
Temperature Reference: 25°C Default? ✓ Yes ____ No
Conductivity Standard: 1413 uS
Conductivity Standard @ 25C: 1413 uS @ 25°C
Successful Calibration? ✓ Yes ____ No
If No, List Corrective Action: ____
Signature: [signature]

Instrument: Dissolved Oxygen Meter
Manufacturer / Model: OxyGuard Handy Polaris 2
Date / Time of Calibration: 3-25-13 17:00
Calibration Method: auto
Initial DO Saturation Reading: 104 (Should read 100.5%)
Calibration Needed? ✓ Yes ____ No
Calibration Precision: ✓ Field ____ Normal ____ High
Successful Calibration? ✓ Yes ____ No → reads 101%
If No, List Corrective Action: ____

Grassy Mountain Ground Water Monitoring Sampling Form

Well No.: PW-4
Personnel: J Thompson
Date: 6-17-13
SPF Sounder #: SPF WL 300-01
Sounder Correction: _____
Weather: clear sunny
Wat Lev Transducer Download? Y _____ N ✓

Page No.: 1 of 1
Photos (#,Name): 8 Yes

GPS Coord. (UTM 11N, NAD83)
Northing: 4838778
Easting: 470535

Well Description
Surface Casing Diam (in): 6 lower is 10"
Well Casing Diam (in): 6
Surface Casing Height AGL (ft): 3
WL Meas Point Desc: top of sounder coupler = 0.16' above cap
Const Depth [ft, BMP]: 375
Locked? Y _____ N ✓ new cover not locked
Well Condition: good

Pump Description
Permanent: ✓ Temporary: _____
Type: grundfos HP: 1.5
Setting Depth (ft): 147 blw toc
Drop Pipe Diam (in): 1.25
Notes: perm pump

Water Quality
Sample Time: 11:20
Field Filtered? Y ✓ N _____
Samples Filtered: Metals + per lab

Grassy Mountain Spring Monitoring Sampling Form

Spring Name: Twin Springs North Page No.: 1 of 1

Personnel: Cameron Carlson

Date: 3/22/17 Photos (#,Name): 27 & 28

Weather: Sunny w/ clouds, high 50's, light variable breeze

GPS Coord. (UTM 11N, NAD83)

Northing: _____ Easting: _____

Spring Source Description Twin Springs North Source.

*Stock tank is vegetated w/ algae & plants growing inside.

Spring Sampling Point Description Discharge is taken from inlet pipe above stock tank w/ 1 liter nalgene container. Stock tank is 3/4 full.

Spring Flow Rate (gpm) 1.76 (Volume: 1000 mL Time: 9.06 s)

1000 mL 8.91 s

1000 mL 9.01 s

Grassy Mountain Spring Monitoring Sampling Form

Spring Name: Lowe Spring Page No.: 1 of 1

Personnel: Sean Albertson

Date: 6/26/18 Photos (#,Name): 23, 24, 25

Weather: Sunny, 80s

GPS Coord. (UTM 11N, NAD83)

Northing: _____ Easting: _____

Spring Source Description Unknown, Broken HDPE pipe sticking out of hillside discharges onto muddy ground below. Nearby stock tank empty. Ground drier around tank than during previous measurement.

Spring Sampling Point Description Flow measured at broken HDPE. May not be representative of total flow due to multiple streams

Spring Flow Rate (gpm) 0.09 (Volume: 200mL Time: 34.36s, 33.92s, 33.98s)

Grassy Mountain Spring Monitoring Sampling Form

Spring Name: Government Corral Page No.: 1 of 1

Personnel: Sean Albertson

Date: 6/26/2018 Photos (#,Name): 26, 27, 28, 29

Weather: Sunny, 80s

GPS Coord. (UTM 11N, NAD83)

Northing: _____ Easting: _____

Spring Source Description Government Corral Springs. Inlet pipe discharges to uppermost stock tank. Water then flows into second tank, then into outlet pipe. Outlet pipe dives and carries water to lowest stock tank ~ 100 yds downhill. Lowest tank drains to ground. Upper tanks fill.

Spring Sampling Point Description Flow measured at inlet pipe to uppermost stock tank. Flow from upper to lower tank measured at outlet of pipe between tanks (in lowest tank)

Spring Flow Rate (gpm) 1.66 (Volume: 1000mL Time: 9.17s) Upper Tank

9.82s

Grassy Mountain Spring Monitoring Sampling Form

Spring Name: Sagebrush Springs Page No.: 1 of 1

Personnel: Sean Albertson

Date: 6/26/2018 Photos (#,Name): 30, 31, 32, 33

Weather: Sunny, 80s

GPS Coord. (UTM 11N, NAD83)

Northing: _____ Easting: _____

Spring Source Description Sagebrush Springs source. Inlet pipe discharges into upper circular tire trough. Outlet of upper trough carries water to lower circular tire trough ~10 yds away. Fiberglass trough uphill of upper tire trough is empty. Two rectangular concrete troughs near upper tire trough dry. Upper tire trough covered in algae.

Spring Sampling Point Description Inlet to upper tire tank just above waterline. Difficult to measure. Lower tire tank inlet submerged, cannot be measured.

Spring Flow Rate (gpm) 1.39 (Volume: 500 mL Time: 5.91 s, 5.78 s, 5.43 s)

1. INTRODUCTION

1.1. Background

A *Final Work Plan* (Plan) *for Grassy Mountain Monitoring Wells* prepared by SPF Water Engineering (SPF) dated November 28, 2016, was approved by the State of Oregon Technical Review Team (TRT) by letter dated January 6, 2017. The Plan described the location, construction, testing, and sampling of five proposed monitoring wells for Calico Resources USA Corp (Calico). These monitoring wells were proposed in the vicinity of the deposit for the purpose of aquifer characterization and to better understand the potential impacts of groundwater on mining operations, including potential dewatering requirements.

The two downgradient shallow wells (GMW17-31 and GMW17-33) and the downgradient deep well (GMW17-32) were constructed and tested in August through November of 2017. One upgradient deep well (GMW18-34) was completed in June of 2018.

The Plan also contemplated an upgradient shallow well. A Work Plan Adjustment dated March 22, 2018, proposed that the shallow well not be constructed if a shallow aquifer is not encountered during drilling of the upgradient deep well. The TRT approved the Work Plan Adjustment by letter dated May 31, 2018. Drilling of the deep upgradient well did not encounter shallow water, so the shallow upgradient well was not constructed.

This well completion report describes the drilling, construction, testing, and water quality sampling from the two downgradient shallow wells (GMW17-31 and GMW17-33) and the upgradient deep well (GMW18-34). A separate well completion report for the downgradient deep well (GMW17-32), dated August 20, 2018, has already been prepared and submitted to the TRT.

1.2. Site Location and Ownership

The downgradient wells are located in the SE¼ of the NW¼ of Section 8, T22S R44E. GMW17-31 is located approximately 800 feet north of the deposit and about 50 feet east of the pre-existing deep monitoring well 59762. GMW17-31 was constructed as the shallow pair to 59762. GMW17-33 is located approximately 600 feet northwest of the deposit. This well was constructed as the shallow pair to GMW17-32. The upgradient deep well GMW18-34 is located in the NW¼ of the SE¼ of Section 8, T22S R44E. GMW18-34 is located approximately 300 feet to the south of the deposit (Figure 1).

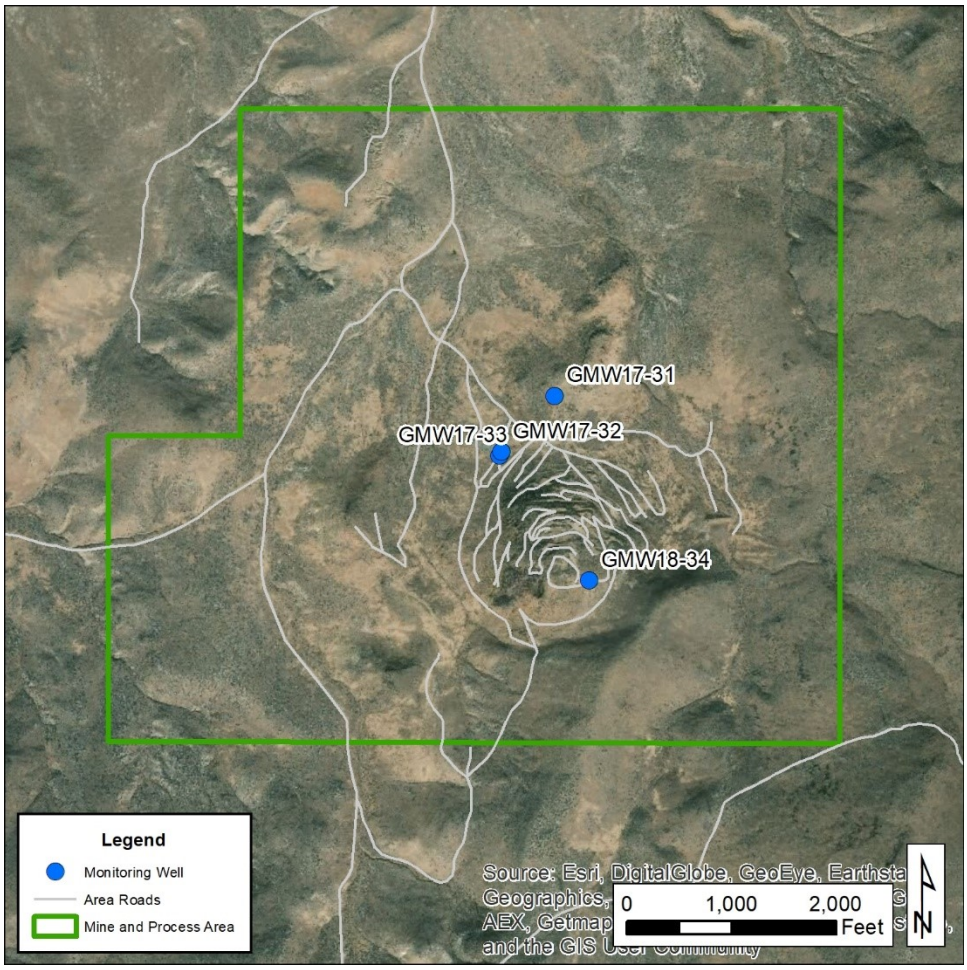

Figure 1. Vicinity map of monitoring wells

2. GMW17-31

2.1. Well Drilling and Construction

2.1.1. Introduction

Well construction began on August 1, 2017, and was completed on August 28, 2017. The well was constructed using the air-rotary method of drilling by Down Right Drilling & Pump Inc. (Down Right), Oregon well driller's license number 1896. The well was constructed under start card number 1035606. The State of Oregon Monitoring Well Report is included in Attachment A.

2.1.2. Surface Casing Installation and Seal

As the first step in the well construction process, a nominal 10-inch borehole was drilled to 150 feet through the surface overburden (0 to 8 feet), sandstone, siltstone and clay (8 to 41 feet), conglomerate, sandstone, siltstone (trace of silicified siltstone), and clay (41 to 60 feet), clay (60 to 147 feet), and sandstone, siltstone, and tuff (147 to 150 feet). The

lithologic log prepared by Calico geologist Michael McGinnis is included in Attachment B. The 10-inch bore was then reamed to a 16-inch bore from the surface to 98 feet for installation of a 12-inch casing.

A nominal 12-inch diameter mild steel casing with 0.250-inch wall thickness was installed from approximately 36 inches above ground surface to a depth of 98 feet. The annulus between the 12-inch casing and the 16-inch bore was sealed from 98 to 38 feet with 49 ft^3 of Portland type I/II neat cement grout pumped through a tremie pipe from the bottom up. This volume of cement is approximately 151% the calculated volume of a 60-foot-long 12.5-inch (casing outside diameter) to 16-inch annulus. The surface seal was completed from 38 feet up to ground surface using 25 ft^3 of bentonite chips. This volume of bentonite chip is approximately 122% the calculated volume of a 38-foot-long 12.5-inch to 16-inch annulus.

2.1.3. Borehole Drilling

Following installation and sealing of the surface casing, the original nominal 10-inch bore was cleaned out to 150 feet and then advanced from 150 to 520 feet by air rotary drilling. No water was encountered during the drilling. Drilling encountered the following lithology as described on the lithologic log in Attachment B:

- sandstone, arkose, siltstone, and tuff to a depth of 247 feet, with an increase in clay (up to 40%) 182-197 feet and 227-247 feet
- sinter and siltstone to 267 feet
- clay with siltstone and tuff to 322 feet
- sinter with silicified siltstone to 347 feet
- arkose with minor tuff and clay to 392 feet
- sinter to 417 feet
- arkose, tuff, and sinter to 432 feet
- siltstone, tuff, silicified siltstone, and clay to 520 feet

Traces of silicified siltstone were observed as shallow as 41 feet and were encountered sporadically throughout the rest of the lithology. No water was encountered during the drilling. The borehole was unstable and required re-drilling with the air-rotary rig and a cable-tool rig to keep the bore open for well completion.

2.1.4. Casing and Screen Placement

Prior to placing casing and screen, the bottom of the 10-inch bore drilled into clay from 520 to 499 feet was backfilled with 11 ft^3 of Portland type I/II neat cement grout pumped through a tremie pipe from the bottom up. This volume of cement is approximately 94% the calculated volume of a 21-foot-long 10-inch bore.

The well was completed with a single string of nominal 5-inch diameter flush-joint Schedule 80 PVC casing and screen. The casing was set from approximately 2 feet above ground surface to a depth of 458 feet, with screen (slot size 0.020-inch) set from a depth of 458 to 498 feet. The 5-inch casing was fitted with centralizers every 60 feet to maintain a consistent annular space inside the 10-inch bore.

2.1.5. Filter Pack

Filter pack (No. 8-12 Colorado Silica Sand) was placed in the annular space outside the 5-inch screens and casing, from 455 to 499 feet. A filter pack seal was installed using No. 20-40 Colorado Silica Sand filter pack placed from 453 to 455 feet to prevent cement intrusion into the underlying filter pack during seal placement. All filter pack was washed into place through flush-joint PVC tremie pipe.

2.1.6. Seal Placement

Following installation of the 5-inch PVC casing and screen and filter pack, tremie pipe was set to approximately 450 feet (3 feet above the top of the filter pack seal) and 240 ft^3 of bentonite-cement grout was pressure-grouted into the annulus between the 5-inch PVC casing, the 10-inch bore, and 12-inch surface casing. The seal was placed from a depth of 453 feet to ground surface. The grout volume required was approximately 124% the calculated volume based on the annulus dimensions mentioned above. The bentonite-cement grout consisted of 3.75 pounds of bentonite (Wyo-Ben Groutwell DF) per 94-lb sack of Portland type I/II neat cement with 7.8 gallons of water.

2.1.7. Well Head Assembly

The 12-inch surface casing extends approximately 36 inches above ground level. The surface casing serves as a protective well shelter for the PVC well casing. The surface casing is fitted with a locking cap to secure the well head. The top of the 5-inch PVC casing is approximately 2 feet above ground level and is fitted with a vented, removable sanitary well cap.

The OWRD well tag is permanently affixed to the 12-inch surface casing by means of a stainless-steel band. A concrete pad (3 feet square) was poured around the well head shelter. Three protective bollards were placed around the well shelter.

Photographs of the well head assembly are provided in Attachment C.

2.1.8. As-Built Schematic

The as-built construction for the well is provided as Attachment D.

2.1.9. Well Development

No water was encountered during drilling the well. Airlifting at the bottom of the well while cleaning infill did not produce water other than minor water injected to remove cuttings. No development was deemed necessary.

2.2. Test Pumping and Water Quality

2.2.1. Well Testing

This well was dry after completion so it could not be test pumped. During quarterly water-level monitoring events on September 26, 2017, and November 29, 2017, the well was checked and confirmed to still be dry. During the most recent two quarterly monitoring events, water was detected in the bottom of the well. On March 7, 2018 and June 26, 2018, the water level was measured at 499.30 and 499.35 feet below the measuring point

with a total amount of water in the bottom being approximately 0.70 and 0.75 feet respectively. The presence of water suggests that the formation is saturated but with a very low hydraulic conductivity. This well will continue to be monitored quarterly to detect any changes in water level.

2.2.2. Water Quality

This well was dry after completion so it could not be sampled for water quality. Since March 2018, a minor amount of water has been detected in the bottom of the well. However, the minor amount of water in the well and extremely low aquifer hydraulic conductivity does not make it suitable for sampling.

2.3. Well Construction and Testing Summary

Grassy Mountain Monitoring Well GMW17-31 was constructed in accordance with the approved Plan and State of Oregon monitoring well construction standards (Administrative Rules Chapter 260, Division 240, dated September 6, 2016). The surface seal was installed to a depth of 453 feet, into a layer of tan/gray clay and siltstone above the target aquifer zone. The surface seal as installed is adequate to prevent any surface contamination from reaching the screened interval.

Following construction, the well was dry so no test pumping or water quality sampling occurred. Since March 2018 a minor amount of water has been detected in the bottom of the well, suggesting that the formation is saturated but exhibits a very low hydraulic conductivity.

3. GMW17-33

3.1. Drilling, Construction, and Development

3.1.1. Introduction

Well construction began on November 2, 2017 and was completed on November 30, 2017. The well was constructed using the air-rotary method of drilling by Down Right. The well was constructed under start card number 1036990. The State of Oregon Monitoring Well Report is included in Attachment A.

3.1.2. Surface Casing Installation and Seal

As the first step in the well construction process, a nominal 10-inch borehole was drilled to 118 feet through the overburden (0 to 10 feet), siltstone/claystone and clay (10 to 40 feet), conglomerate, sandstone, and siltstone (40 to 50 feet), tuff and clay with some siltstone, and sandstone (50 to 118 feet). The lithologic log is included in Attachment B. The 10-inch bore was then reamed to a 16-inch bore to 118 feet for installation of a 12-inch surface casing.

A nominal 12-inch diameter mild steel casing with 0.250-wall thickness was installed from approximately 34 inches above ground surface to a depth of 118 feet. The annulus between the 12-inch casing and the 16-inch bore was sealed from 118 feet to ground

surface with 82.8 ft^3 of Portland type I/II neat cement grout pumped through a tremie pipe from the bottom up. This volume of cement is approximately 129% the calculated volume needed for a 118-foot long, 12.5-inch (casing outside diameter) to 16-inch, annulus.

3.1.3. Borehole Drilling

Following installation and sealing of the surface casing, a nominal 12-inch bore was advanced from 118 to 365 feet by air-rotary drilling. Drilling encountered the following lithology as described on the lithologic log in Attachment B.

- clay with tuff and arkose to a depth of 120 feet
- arkose with sinter and tuff to 150 feet
- sandstone and siltstone with arkose to 160 feet
- clay and arkose with some sinter to 170 feet
- sinter with sandstone, arkose and clay to 190 feet
- clay to 210 feet
- arkose with clay to 220 feet
- clay and arkose to 235 feet
- sinter and silicified siltstone with traces of tuff and clay to 290 feet
- clay to 295 feet
- sinter to 300 feet
- silicified siltstone, sinter and tuff with traces of clay to 365 feet

The lithology is weak to moderately silicified from a depth of 235 feet to 365 feet. Water was first encountered at 240 feet. The hole was drilled to the total depth of 365 feet by November 18, 2017. The bore had caved up to 339 feet prior to the casing, screens, and sand being installed.

3.1.4. Casing and Screen Placement

The well was completed with a single string of nominal 5-inch diameter flush-joint Schedule 80 PVC casing and screen. The casing was set from approximately 2 feet above ground surface to a depth of 238 feet, with screen (slot size 0.020-inch) set from a depth of 238 to 338 feet. The 5-inch casing was fitted with centralizers every 60 feet to maintain a consistent annular space inside the 12-inch bore and casing.

3.1.5. Filter Pack

Filter pack (No. 10-20 Colorado Silica Sand) was placed in the annular space outside the 5-inch screen and casing from a depth of 235 to 339 feet. A filter pack seal consisting of No. 20-40 Colorado Silica Sand filter pack was placed from 233 to 235 feet to prevent cement intrusion into the underlying filter pack during seal placement. All filter pack was washed into place through tremie pipe.

3.1.6. Seal Placement

Following installation of the 5-inch PVC casing and screen and filter pack, tremie pipe was set to 233 feet (top of the filter pack seal) and 158.4 ft^3 of a bentonite-cement grout was pressure grouted in the annulus between the 5-inch PVC casing and the 12-inch steel casing and 12-inch bore. The seal was placed from a depth of 233 feet to ground surface.

This grout volume required was approximately 110% of the calculated volume based on the annulus dimensions mentioned above. The bentonite-cement grout consisted of 3.75 pounds of bentonite (Wyo-Ben Groutwell DF) per 94-lb sack of Portland type I/II neat cement with 7.8 gallons of water.

3.1.7. Well Head Assembly

The 12-inch surface casing extends approximately 3 feet above ground level. The surface casing serves as a protective well shelter for the PVC well casing. The surface casing is fitted with a locking cap to secure the well head. The top of the 5-inch PVC casing is approximately 2 feet above ground level and is fitted with a vented, removable sanitary well cap.

The OWRD well tag is permanently affixed to the 12-inch surface casing by means of a stainless-steel band. A concrete pad (3 feet square) was poured around the well head shelter. Three protective bollards were placed around the well shelter.

Photographs of the well head assembly are provided in Attachment C.

3.1.8. As-Built Schematic

The as-built construction schematic for the well is provided as Attachment D.

3.1.9. Well Development

After completion, Well GMW17-33 was bailed for 7 hours with a 3-inch bailer then development pumped at approximately 30 to 40 gpm for 2 hours. Development pumping ended on December 8, 2017, at 17:31. The well produced some fine sand and silts during development. At the end of development, the well was not producing sediment and the water was clear.

3.2. Test Pumping and Water Quality

3.2.1. Well Testing

Monitoring Well GMW17-33 was tested on December 14, 2017 using a 5 hp A.Y. McDonald Mfg. Co. 24500R 35-gpm submersible pump. The pump was supplied by Down Right Drilling and set on 2-inch drop pipe at a depth of approximately 340 feet below the measuring point, 1 foot from the bottom of the well and 102 feet below the top of the screen interval. A 1.25-inch PVC sounding tube was installed to the top of the pump. After installation the pump was operated for 2 hours to assess operation and confirm proper development.

Prior to testing, a water-level pressure transducer was installed in the well to automatically record water levels at one-minute intervals. The pressure data was corrected for barometric pressure. The test pumping was supervised by Kurt Newbry, P.G. from SPF. Manual water-level measurements were made by Kurt Newbry and Down Right using a non-stretch well sounder. Flow was measured and totalized with a 4-inch Siemens Mag flow meter and confirmed throughout testing with a 5-gallon bucket and stopwatch.

During the test, the water level was measured relative to the top of the 1.25-inch sounding tube which was 1.06 feet above the top of the 5-inch PVC casing. All reported water levels

have been corrected to reference the long-term measuring point of the top of the 5-inch PVC casing (approximately 2 feet above ground level).

Test pumping of the well began on December 14, 2017, at 14:00, or about 20.5 hours after development pumping ended. The static water level prior to testing was 243.07 feet below the measuring point which was less than one foot deeper than the static water level measured prior to pumping the day before. The initial constant pumping rate was approximately 30 gpm. The first 3,220 minutes (53.7 hours) of the test showed sustainable drawdown with minor negative and positive boundary effects or possible delayed yield effects. After 3,220 minutes, a major negative boundary effect was observed. To avoid the pump breaking suction, as well as an attempt to prolong the test, the flow rate was then decreased to 27 gpm at 3,465 minutes, 25 gpm at 3,575 minutes, 20 gpm at 4,050 minutes, and 17.5 gpm at 4,678 minutes. The pump was eventually turned off at 5,820 minutes (97 hours) with the end pumping rate at 17.2 gpm and an average pumping rate of 25.8 gpm over the pumping period. The total drawdown in the well at the end of the pumping period was approximately 46 feet, but the maximum drawdown reached was around 91 feet at the 27-, 25-, and 20-gpm pumping rates.

An arithmetic time series plot showing brief operation of pump for testing and well development, test pumping, and recovery until December 20, 2017, is presented as Figure 2. The short recovery period is displayed to show pumping water level changes more clearly. Test pumping data are provided as Attachment E.

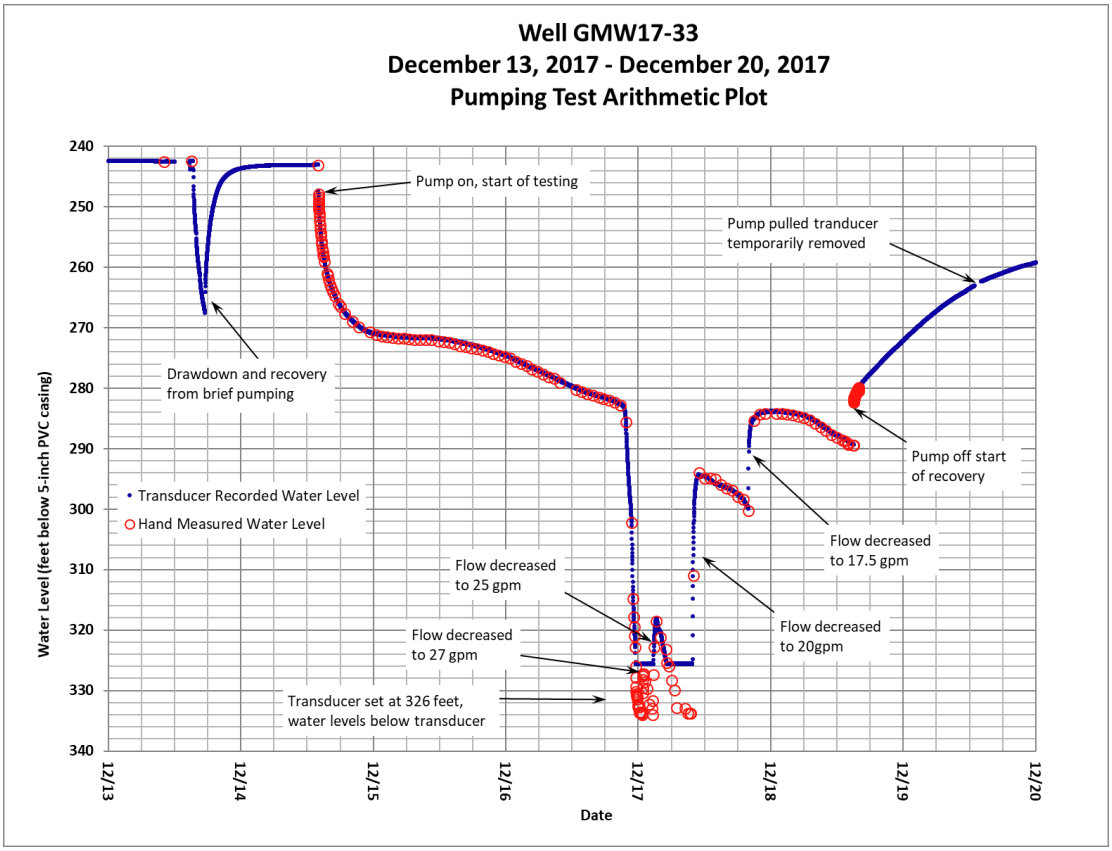

Figure 2. GMW17-33 pumping test arithmetic plot

An additional arithmetic time series plot showing longer pre-testing and post-testing water levels is provided as Figure 3.

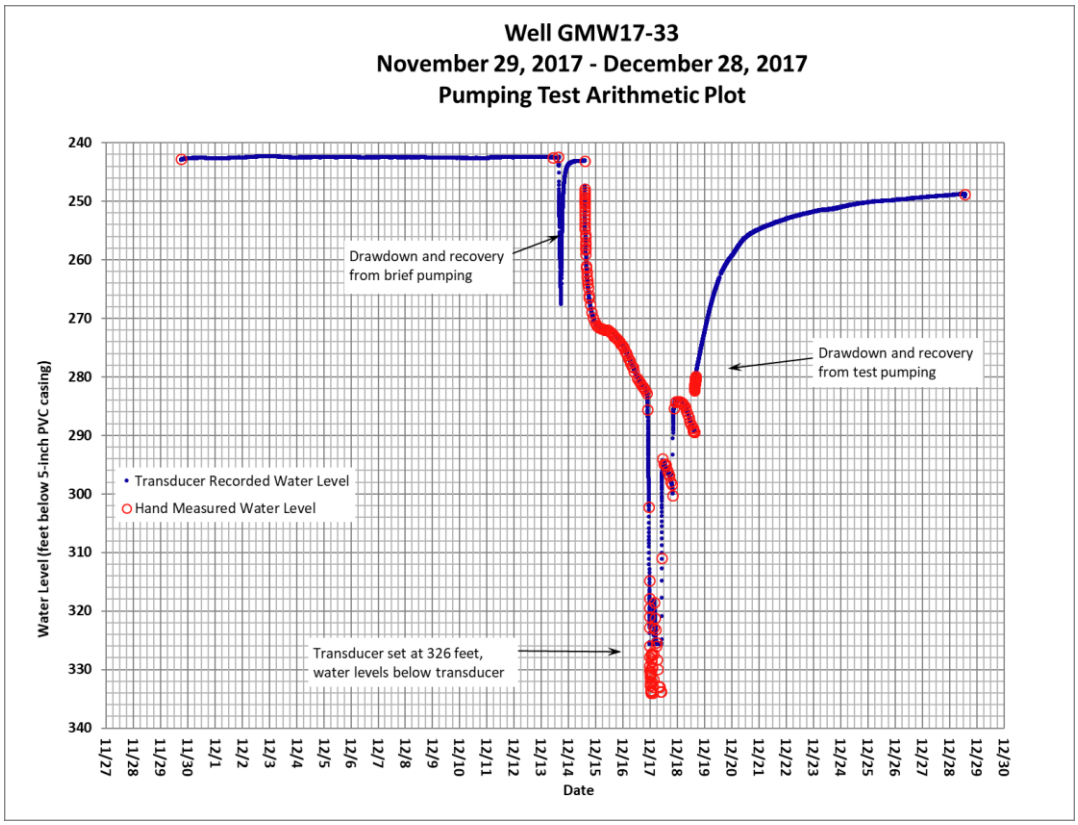

Figure 3. GMW17-33 pumping test arithmetic plot with a longer timespan

3.2.2. Aquifer Characteristics

3.2.2.1. Aquifer Transmisivity

A semi-log plot of the drawdown data is presented below as Figure 4. Transmissivity was estimated using Cooper-Jacob straight line methods on a semi-log plot of drawdown versus elapsed time for the pumping portion of the aquifer test. The transmissivity obtained from a match to the early-time data using an average pumping rate of 25.8 gpm was approximately 500 gpd/ft (70 ft^2/d). Approximately 500 minutes into the pumping test, the drawdown appeared to stabilize for about 1 day, possibly attributed to delayed yield effects, followed by a negative boundary effect after approximately 3,200 minutes of pumping. Assuming an aquifer thickness of 200 feet, the estimated hydraulic conductivity near the well would be approximately 0.4 ft/d (encountered within one day of pumping). If only the screened interval contributed flow to the well with a saturated thickness of 97 feet, the estimated hydraulic conductivity would be approximately 0.7 ft/d. The hydraulic conductivity encountered at the negative boundary would be significantly less based on increased and unsustainable drawdown effects.

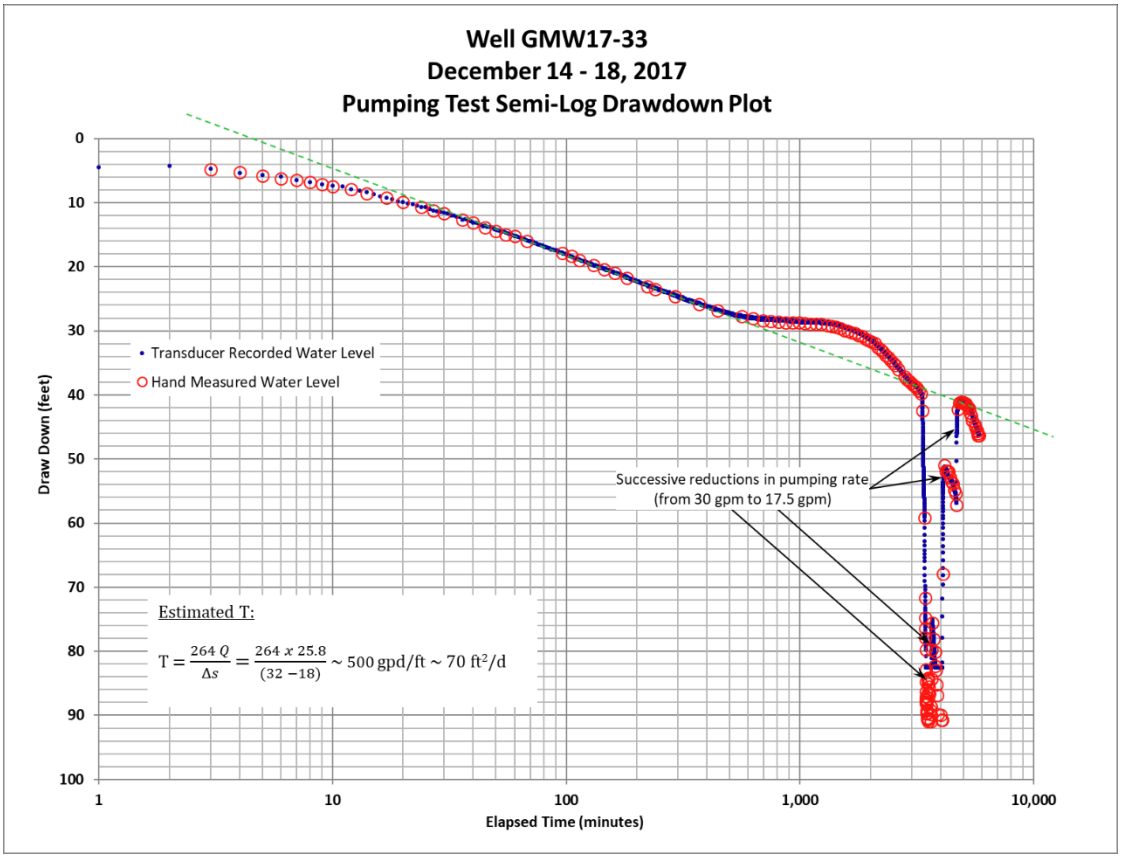

Figure 4. Well GMW17-33 aquifer test pumping drawdown analysis

A semi-log plot of the recovery data collected following the test pumping until March 7, 2018 is presented below as Figure 5. Using the recovery data and an average pumping rate of 25.8 gpm, an aquifer transmissivity of approximately 6,800 gpd/ft (900 ft^2/day) was estimated using the early time data and an aquifer transmissivity of approximately 340 gpd/ft (50 ft^2/day) was estimated using the late time data. Assuming only the screened interval contributed flow to the well with a saturated thickness of 97 feet, the assumed hydraulic conductivity would be 10 ft/d near the well, and 1 ft/d at the boundary. This response suggests compartmentalization of the aquifer, with higher versus lower permeability zones,

Quarterly monitoring of the of GMW17-33 showed the water level was still recovering on March 7, 2018, with a water level of 246.21 feet below the measuring point (approximately 3.14 feet of residual drawdown from the pre-test static water level). On June 26, 2018, this water level was measured at 249.38 feet below the measuring point, a 3.17-foot drop in water level since the last quarterly measurement. Water levels in this well will continue to be monitored on a quarterly basis.

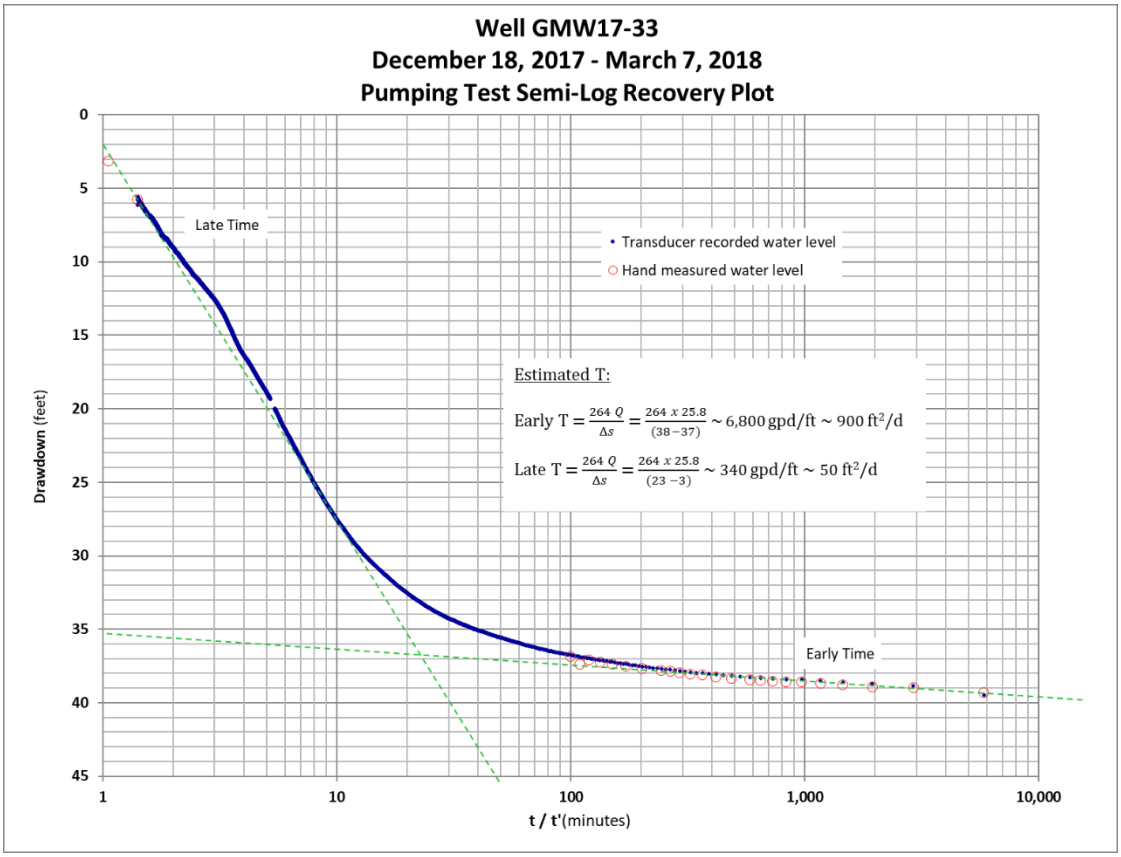

Figure 5. Well GMW17-33 aquifer test recovery analysis

3.2.2.2. Response in Nearby Wells

During the testing of GMW17-33, water levels were measured in nearby wells using water level transducers and manual measurements with a non-stretch well sounder. Pressure transducers were installed in wells 59762, GMW17-32 (deep pair to GMW17-33), GW-3, 26-92-915, BLM, PW-1, GW-1, 57-10, 59761, 59772, GW-2, and GW-4. The water level plots show that there was no measurable response observed in any of the wells as a result of testing GMW17-33. In return, during the testing of GMW17-32 and 59762, there was no water level response in in GMW17-33. Plots showing the water levels in each of the monitoring wells are provided in Attachment E.

3.2.3. Water Quality

3.2.3.1. Field Water Quality

Field water quality data were collected from the start of the test until water quality sampling. Results are summarized in Table 1 below. The pH measured throughout the test pumping is unusually low, with a value of 6.95 measured right before sample collection. The laboratory reported a pH of 8.1, more than one standard unit higher than the pH measured in the field. A pH of around 8 is expected based on the nearby wells. The field pH unit appears to have been in error, despite recent calibration of the pH meter. The conductivity values are lower than expected with a value of 268 µS/cm measured right before sample collection. The laboratory reported a conductivity of 477 µS/cm. The field conductivity meter also appears to have been reporting erroneous values. It was very cold on the day of sampling and that may have affected the field water quality measurements. A Grassy Mountain groundwater monitoring sampling form is provided in Attachment F.

Table 1. GMW17-33 field water quality data

Time	pH (S.U.)	EC (µS/cm)	SC (µS/cm @ 25°C)	Temp. (°C)	DO (mg/L)	Notes
14:00						pump on
14:27	6.46	319	388	15.7	2.75	clear, medium degassing, no odor, no sand
14:45	6.78	315	383	15.7	2.35	
15:08	6.88	312	379	15.7	2.17	
17:04	6.95	278	338	15.7	1.66	
17:42	6.95	274	333	15.6	1.7	
18:00	6.95	268	327	15.7	1.68	clear, medium degassing, no odor, no sand

3.2.3.2. Laboratory Water Quality

Water quality samples were collected by Kurt Newbry with SPF after 4 hours of pumping at 30 gpm on December 14, 2017 at 18:00. Samples were collected from a sample tap in the discharge piping while pumping at approximately 30 gpm. The water was clear, showed signs of degassing, had no apparent odor, and no sand. Water quality sampling procedures and quality assurance/quality control were conducted per the Environmental Baseline Study Work Plans (Work Plans) for the Grassy Mountain Project dated May 17, 2017.

A total of 7,200 gallons was pumped from the well prior to sampling, equal to more than 70 casing volumes of water. Samples were collected for the water quality analytes listed in Table 15 of Section 3.4.4.2.11 of the Work Plans, as amended to include uranium,

replace nitrate and nitrite sampling with combined nitrate+nitrite, and remove inorganic arsenic. The samples were shipped to ACZ Laboratories (ACZ) in Steamboat Springs, Colorado on December 15, 2017. The samples were received by ACZ at a temperature of 2.5°C, below the upper limit of 6°C. The field form and laboratory report are provided in Attachment F.

3.2.3.3. Water Quality Comparison to Drinking Water Standards

Water quality analytical results were compared to Environmental Protection Agency (EPA) primary and secondary drinking water standards. Primary drinking water standards are legally enforceable standards meant to protect public health. The enforceable standards are referred to as maximum contaminant levels (MCLs). Secondary drinking water standards are non-enforceable water quality standards meant to address aesthetic concerns with drinking water, including taste, color, and odor. Secondary standards do not present a public health risk.

The water quality parameters from GMW17-33 exceeding primary or secondary drinking water standards are summarized in Table 2. A total of two analytes exceed their respective MCL; both the total and dissolved concentrations of antimony and arsenic exceeded the MCL.

Primary drinking water analytes over the minimal detection limit include barium at 0.008 mg/L, beryllium at 0.00007 mg/L, copper at 0.0005 mg/L, lead at 0.002 mg/L, mercury at 11.5 ng/L, selenium at 0.0106 mg/L, uranium at 0.0007 mg/L, and nitrate+nitrite at 1.46 mg/L. Nitrate+nitrite, which does not have an MCL, was used as a substitute for nitrate and nitrite in this study. The MCL values for nitrate and nitrite are 10 mg/L and 1 mg/L respectively.

Table 2. GMW17-33 water quality results exceeding drinking water standards

Parameter	**MCL (mg/L)**	**12-11-17 Sample Result (mg/L)[1]**
Antimony, dissolved	0.006	0.0217
Antimony, total	0.006	0.0244
Arsenic, dissolved	0.01	0.106
Arsenic, total	0.01	0.107

3.2.3.4. Major Ion Chemistry

Geochemical characteristics of the groundwater from GMW17-33 were evaluated using Piper diagrams (also known as Trilinear diagrams) and Stiff diagrams, with major ions expressed as meq/L. These diagrams are useful for evaluating the geochemical signature of the water, to illustrate general differences in water chemistry using major ions, and to group waters with similar chemical signature into identifiable groups.

The Stiff diagram for GMW17-33 is presented as Figure 6. The Stiff diagram identifies the groundwater as having a sodium-potassium sulfate (Na/K-SO4) water quality signature with bicarbonate almost as prominent as sulfate. For comparison, the nearby deep well 59762 has the same signature.

The Piper diagram for the groundwater quality data from GMW17-33 and the 3rd Quarter 2014 data from all other wells is presented as Figure 7. The Piper diagram also shows a sodium-potassium sulfate (Na/K-SO4) water quality signature for GMW17-33.

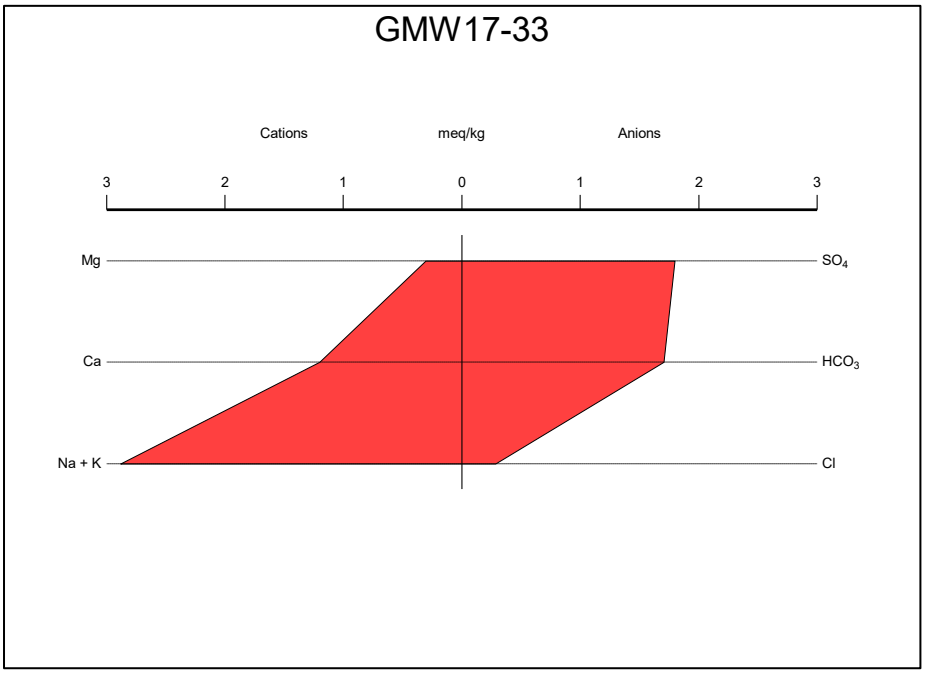

Figure 6. Stiff diagram for GMW17-33

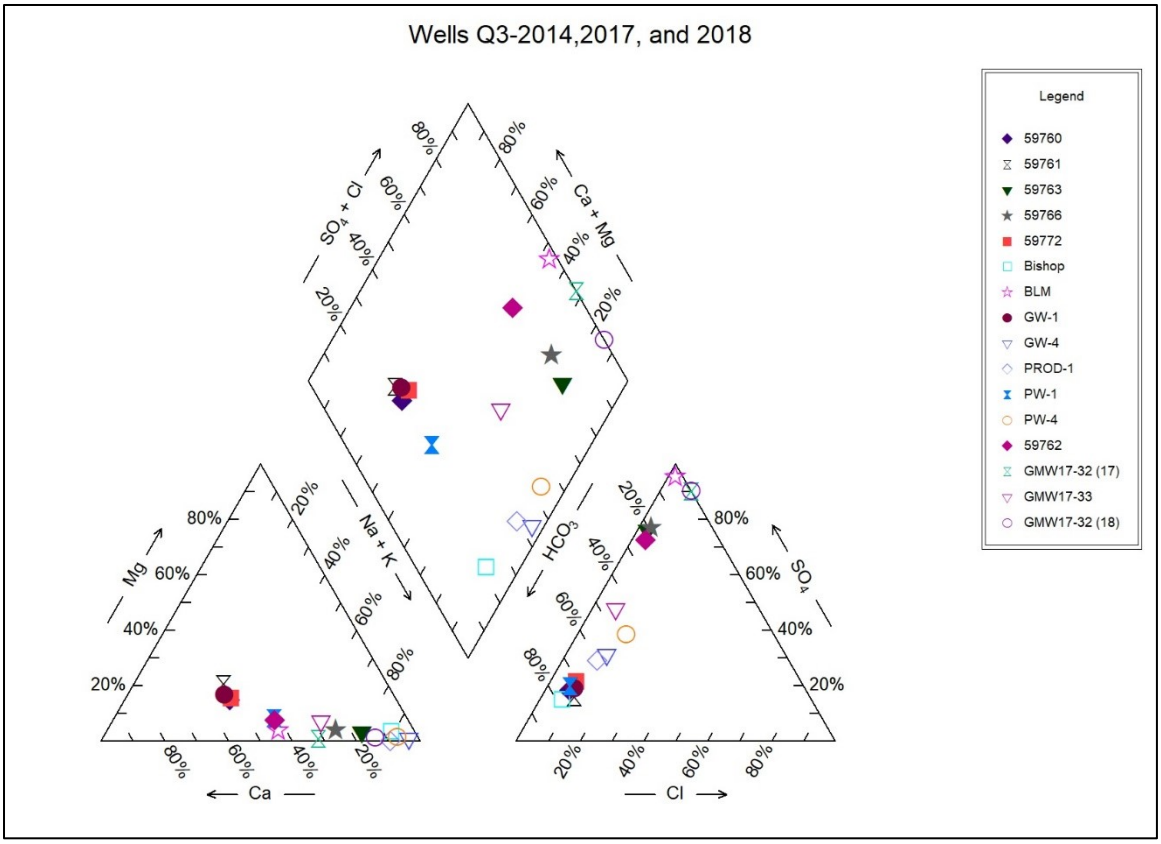

Figure 7. Piper diagram for GMW17-33

3.3. Well Construction and Testing Summary

Grassy Mountain Monitoring Well GMW17-33 was constructed in accordance with the approved Plan and State of Oregon monitoring well construction standards (Administrative Rules Chapter 260, Division 240, dated September 6, 2016). The surface seal was installed to a depth of 233 feet, below multiple layers of clay and siltstone above the target aquifer. The surface seal as installed is adequate to prevent any surface contamination from reaching the aquifer.

Upon initial testing the well produced 30 gpm. After approximately 3,200 minutes a negative boundary affect was observed and the water level declined significantly with an increase of the drawdown per log cycle to over 100 times the early time water level drawdown. The pumping rate was decreased to 27, 25, 20.5, and 17.5 gpm in an attempt to obtain a steady drawdown without the water level drawing down to the pump intake. During the flow decreases the water level would recover, but then continue to drop to unsustainable drawdown conditions. It seems that once the local bounded aquifer was drained, the recharge was significantly impeded by hydraulic boundaries (structural disconformities and/or very low permeability strata).

The groundwater sampling results show this well having a sodium-potassium sulfate (Na/K-SO4) water quality signature with bicarbonate measuring in almost as prominent as sulfate. Two water quality analytes from GMW17-33 exceed the primary drinking water

standards. Antimony (total) was detected at 0.0244 mg/L (MCL = 0.006 mg/L) and arsenic (total) was detected and 0.107 mg/L (MCL = 0.01 mg/L).

4. GMW18-34

4.1. Well Drilling and Construction

4.1.1. Introduction

Well construction began on April 17, 2018, and was completed on June 21, 2018. The well was constructed using the air-rotary method of drilling by Down Right. The well was constructed under start card number 1038395. The State of Oregon Supply Well Report is included in Attachment A.

4.1.2. Surface Casing Installation and Seal

As the first step in the well construction process, a nominal 10-inch borehole was drilled to 200 feet through the surface overburden with arkose (0 to 5 feet), silicified arkose (5 to 20), tuffaceous siltstone (20 to 35 feet), tuff (35 to 45 feet), arkose (45 to 70 feet), tuff (70 to 75 feet), clay and arkose (75 to 135 feet), tuff and clay (135 to 175 feet), and sinter and arkose (175 to 200 feet). The lithologic log is included in Attachment B. The 10-inch bore was then reamed to a 16-inch bore from the surface to 200 feet for installation of a 12-inch casing.

A nominal 12-inch diameter mild steel casing with 0.375-inch wall thickness was installed and an under-reaming bit was used to advance the casing to 355 feet. The top 58 feet of the 12-inch diameter mild steel casing is 0.250-inch wall thickness. The under-reaming bit was able to drill a 14-inch bore to advance the 12-inch diameter casing. The borehole was drilled from 200 to 355 feet through arkose and tuff (200 to 230 feet), and sinter with traces of clay, tuff, and silicified siltstone (230 to 355 feet).

The 12-inch casing was sealed into place from approximately 3 feet above ground surface to a depth of 355 feet. The annulus between the 12.75-inch (O.D.) casing and the 14-inch bore was sealed from 355 to approximately 200 feet with 32 ft^3 of Portland type I/II neat cement grout. The cement grout was pumped into the bottom of the 12-inch casing then was pushed down and out of the casing and up the annulus using a “dart”. The installed volume of 32 ft^3 is 115% of the calculated volume needed for a 155-foot-long, 12.75-inch to 14-inch annulus.

After sealing the 12-inch casing from the bottom up, a tremie pipe was installed in the 12.75-inch to 16-inch annulus to 199 feet and 84 ft^3 of Portland type I/II neat cement grout was pumped into the annulus. After pumping in this cement, attempts to tag the top of the cement showed it did not come up above 199 feet. It is believed that this cement flowed out fractures in the unsaturated media.

The 12.5-inch and 12.75-inch to 16-inch annulus was then sealed from 199 to 8 feet with 98.7 ft^3 of bentonite chips poured in from the top. The volume of bentonite chip used to

seal this annulus is 100% of the calculated volume for a 144-foot-long, 12.75-inch to 16-inch annulus and 47-foot-long, 12.5-inch to 16-inch annulus.

The top 8 feet of the 12.5-inch to 16-inch annulus was sealed with 9.6 ft^3 of Portland type I/II neat cement grout. This volume is 221% the calculated volume for this annulus, suggesting loss to the formation.

4.1.3. 10-inch Under-Reaming, 12-inch Bore Drilling

Following installation and sealing of the surface casing, a 12-inch open borehole was drilled to 671 feet. Drilling encountered the following lithology as described on the lithologic log in Attachment B:

- siltstone and clay from a depth of 355 to 360 feet
- siltstone and sinter to 380 feet
- clay with sinter and siltstone to 420 feet
- arkose with silicified siltstone to 450 feet
- silicified siltstone and sandstone with arkose to 455 feet
- sinter with siltstone to 465 feet
- arkose with siltstone to 505 feet
- clay and siltstone to 525 feet
- sinter with traces of siltstone, tuff, arkose to 600 feet
- clay siltstone and arkose to 615 feet
- siltstone and arkose to 625 feet
- sinter to 640 feet
- sinter and siltstone to 655 feet
- arkose and siltstone to 671 feet

There was no indication of water during drilling to 671 feet. After drilling 12-inch open hole to 671 feet, the next day the hole had caved up to 630 feet. A nominal 10-inch diameter mild steel casing with 0.250-inch wall thickness was then installed to a depth of 658 feet. The hole was cleaned out to 671 feet. Air-lifting occurred to determine if there was any water present. Starting at a depth of 520 feet, the drill steel was lowered in 20-foot increments, then air-lifting occurred for 15 minutes to detect the presence of water. No water was observed during this process. A bailer was then lowered to the bottom of the hole and no water was bailed from the well.

After it was confirmed no shallow water was present, the 10-inch casing was advanced to 790 feet using a 10-inch under-reaming bit. Drilling during the 10-inch under-reaming encountered the following lithology as described on the lithologic log in attachment B:

- arkose and siltstone from 671 to 705 feet
- silicified siltstone, tuff and sandstone to 730 feet
- tuff with sandstone and siltstone to 745 feet
- arkose and silicified siltstone to 790 feet

No water was encountered during the drilling. The 10-inch casing was then sealed from a depth of 790 feet to ground surface with 148.8 ft^3 of Portland type I/II neat cement grout. This volume is 102% the calculated volume for 790 feet of a 10.5-inch to 12-inch annulus.

4.1.4. 10-inch Borehole Drilling

After the 10-inch casing was sealed, a nominal 10-inch diameter bore was drilled from 790 feet to 950 feet by air-rotary drilling. Drilling encountered the following lithology as described on the lithologic log in Attachment B:

- siltstone and arkose from 790 to 800 feet
- sandstone and siltstone and tuffaceous siltstone to 865 feet
- siltstone and tuffaceous siltstone to 885 feet
- silicified sandstone and siltstone to 895 feet
- clay to 900 feet
- tuff with sandstone and siltstone to 915 feet
- tuff to 950 feet

The lithology is moderately to highly silicified from a depth of 200 feet to 920 feet. The drilling was typically difficult, with layers of swelling clay, hard rock, and fractured pockets where circulation was lost. No water was encountered during drilling.

4.1.5. Casing and Screen Placement

Prior to placing casing and screen, the bottom 58 feet of the 10-inch bore drilled into clay was backfilled with bentonite chips. The well was completed with a single string of nominal 5-inch diameter Schedule 40 stainless steel casing and screen. The casing was set from approximately 2 feet above ground surface to a depth of 830 feet, with screen (slot size 0.030-inch) set from a depth of 830 to 890 feet. The 5-inch casing was fitted with centralizers every 60 feet to maintain a consistent annular space inside the 10-inch bore.

4.1.6. Filter Pack

Filter pack (No. 8-12 Colorado Silica Sand) was placed in the annular space outside the 5-inch screens and casing, from 828 to 892 feet. A filter pack seal using No. 16-30 Colorado Silica Sand filter pack was placed from 826 to 828 feet to prevent cement intrusion into the underlying filter pack during seal placement. All filter pack was washed into place through flush-joint PVC tremie pipe.

4.1.7. Seal Placement

Following installation of the 5-inch PVC casing and screen and filter pack, tremie pipe was set to approximately 826 feet (top of the filter pack seal) and 355.2 ft^3 of Portland type I/II neat cement grout was pressure-grouted into the annulus between the 5-inch PVC casing, the 10-inch bore, and 10-inch casing. The seal was placed from a depth of 826 feet to surface. The grout volume required was approximately 115% the calculated volume based on the annulus dimensions mentioned above.

4.1.8. Well Head Assembly

The 12-inch surface casing extends approximately 36 inches above ground level. The surface casing serves as a protective well shelter for the PVC well casing. The surface casing is fitted with a locking cap to secure the well head. The top of the 5-inch stainless-steel casing is approximately 2 feet above ground level and is fitted with a vented, removable sanitary well cap.

The OWRD well tag is permanently affixed to the 12-inch surface casing by means of a stainless-steel band. A concrete pad (3 feet square) was poured around the well head shelter. Three protective bollards were placed around the well shelter.

Photographs of the well head assembly are provided in Attachment C.

4.1.9. As-Built Schematic

The as-built construction for the well is provided as Attachment D.

4.1.10. Well Development

During drilling the well did not produce water. Airlifting at the bottom of the well while removing infill did not produce water other than minor water injected to remove cuttings. No development was deemed necessary.

4.2. Test Pumping and Water Quality

4.2.1. Well Testing

This well was dry after completion so test pumping was not possible. The well was checked again on June 26, 2018, during quarterly water-level monitoring. A non-stretch well sounder was ran to the bottom of the well and no water was detected. This well will continue to be monitored quarterly to determine if water eventually seeps in the bottom.

4.2.2. Water Quality

This well was dry after completion so it could not be sampled for water quality.

4.3. Well Construction and Testing Summary

Grassy Mountain Monitoring Well GMW17-31 was constructed in accordance with the approved Plan and State of Oregon well construction standards (Administrative Rules Chapter 260, Division 200, dated September 6, 2016). The surface seal was installed to a depth of 355 feet, into a layer of siltstone and clay. The surface seal as installed is adequate to prevent any surface contamination from reaching the aquifer.

Following construction, the well was dry so no test pumping or water quality sampling occurred.

5. SUMMARY

Four groundwater monitoring wells were installed at the Grassy Mountain project site in 2017 and 2018. This report provides details for two downgradient shallow wells (GMW17-31 and GMW17-33) and one upgradient deep well (GMW18-34). A downgradient deep well (GMW17-32) is detailed in a previous report by SPF dated August 20, 2018.

Well GMW17-31 was constructed to a depth of 498 feet. The well was dry upon completion in August 2017, but monitoring in 2018 has shown an accumulated total of slightly less than 1 foot of water in the bottom of the well. The inflow of water into the well is insufficient for test pumping or water quality sampling.

Well GMW17-33 was constructed to a depth of 338 feet. The well produced up to 40 gpm during development pumping. Test pumping was initiated at 30 gpm, but the rate could not be sustained due to apparent dewatering of the compartmentalized aquifer tapped by the well. Water quality samples were obtained from the well for laboratory analysis. The groundwater from this well has a sodium-potassium sulfate (Na/K-SO4) water quality signature. The concentrations of arsenic and antimony exceed the primary drinking water standards.

Well GMW18-34 was constructed to a depth of 890 feet. The well was dry upon completion in June 2018.

An upgradient shallow well was originally proposed. However drilling of the deep upgradient well did not find evidence of a shallow aquifer. The TRT subsequently approved a Work Plan Adjustment not requiring the upgradient shallow well.

Attachment E
GMW18-33 Test Pumping Data and Water Level Graphs from Nearby Wells

Grassy Mountain GMW17-33 Pumping Test
12/14/2017 through 12/18/2017

Tested by Down Right Drilling & Pump. Supervised by Kurt Newbry (SPF Water Engineering).

Pump type: 5-HP Submersible, A.Y. McDonald Mfg. Co. 24500R.

Flow measured with totalized with a Siemens Mag Flow Meter and calibration checked by timing a 5-gallon buckett.

Water level measured with a non-stretch 800-foot Waterline well sounder .

Measurement Point: top of PVC casing approximately 1.5 feet above ground surface.

Date / Time	Elapsed Time (minutes)	t'	t/t'	Water Level (ft bmp, mp = 18" agl)	Draw Down (feet)	Flow (gpm)	Totalizer (million gallons)	Comments

Grassy Mountain GMW17-33 Pumping Test
12/14/2017 through 12/18/2017

Tested by Down Right Drilling & Pump. Supervised by Kurt Newbry (SPF Water Engineering).

Pump type: 5-HP Submersible, A.Y. McDonald Mfg. Co. 24500R.

Flow measured with totalized with a Siemens Mag Flow Meter and calibration checked by timing a 5-gallon buckett.

Water level measured with a non-stretch 800-foot Waterline well sounder .

Measurement Point: top of PVC casing approximately 1.5 feet above ground surface.

Analytical Report

January 05, 2018

Report to:
Jason Thompson
SPF Water Engineering
300 E. Mallard Drive, Suite 350

Boise, ID 83706

cc: Kurt Newbry

Bill to:
Jason Thompson
SPF Water Engineering
300 E Mallard Drive
Suite 350
Boise, ID 83706

Project ID: Calico Monitoring Well Samplin
ACZ Project ID: L41826

Jason Thompson:

Enclosed are the analytical results for sample(s) submitted to ACZ Laboratories, Inc. (ACZ) on December 16, 2017. This project has been assigned to ACZ's project number, L41826. Please reference this number in all future inquiries.

All analyses were performed according to ACZ's Quality Assurance Plan. The enclosed results relate only to the samples received under L41826. Each section of this report has been reviewed and approved by the appropriate Laboratory Supervisor, or a qualified substitute.

Except as noted, the test results for the methods and parameters listed on ACZ's current NELAC certificate letter (#ACZ) meet all requirements of NELAC.

This report shall be used or copied only in its entirety. ACZ is not responsible for the consequences arising from the use of a partial report.

All samples and sub-samples associated with this project will be disposed of after February 04, 2018. If the samples are determined to be hazardous, additional charges apply for disposal (typically $11/sample). If you would like the samples to be held longer than ACZ's stated policy or to be returned, please contact your Project Manager or Customer Service Representative for further details and associated costs. ACZ retains analytical raw data reports for ten years.

If you have any questions or other needs, please contact your Project Manager.

Max Janicek has reviewed and approved this report.

Metals Analysis

Parameter	EPA Method	Dilution	Result	Qual	XQ	Units	MDL	PQL	Date	Analyst
Mercury, total	M1631, Atomic Fluorescence	1		U		ng/L	0.2	0.5	12/21/17 14:07	mfm

Report Header Explanations

Batch	A distinct set of samples analyzed at a specific time
Found	Value of the QC Type of interest
Limit	Upper limit for RPD, in %.
Lower	Lower Recovery Limit, in % (except for LCSS, mg/Kg)
MDL	Method Detection Limit. Same as Minimum Reporting Limit unless omitted or equal to the PQL (see comment #5). Allows for instrument and annual fluctuations.
PCN/SCN	A number assigned to reagents/standards to trace to the manufacturer's certificate of analysis
PQL	Practical Quantitation Limit. Synonymous with the EPA term "minimum level".
QC	True Value of the Control Sample or the amount added to the Spike
Rec	Recovered amount of the true value or spike added, in % (except for LCSS, mg/Kg)
RPD	Relative Percent Difference, calculation used for Duplicate QC Types
Upper	Upper Recovery Limit, in % (except for LCSS, mg/Kg)
Sample	Value of the Sample of interest

QC Sample Types

AS	Analytical Spike (Post Digestion)	*LCSWD*	Laboratory Control Sample - Water Duplicate
ASD	Analytical Spike (Post Digestion) Duplicate	*LFB*	Laboratory Fortified Blank
CCB	Continuing Calibration Blank	*LFM*	Laboratory Fortified Matrix
CCV	Continuing Calibration Verification standard	*LFMD*	Laboratory Fortified Matrix Duplicate
DUP	Sample Duplicate	*LRB*	Laboratory Reagent Blank
ICB	Initial Calibration Blank	*MS*	Matrix Spike
ICV	Initial Calibration Verification standard	*MSD*	Matrix Spike Duplicate
ICSAB	Inter-element Correction Standard - A plus B solutions	*PBS*	Prep Blank - Soil
LCSS	Laboratory Control Sample - Soil	*PBW*	Prep Blank - Water
LCSSD	Laboratory Control Sample - Soil Duplicate	*PQV*	Practical Quantitation Verification standard
LCSW	Laboratory Control Sample - Water	*SDL*	Serial Dilution

QC Sample Type Explanations

Blanks	Verifies that there is no or minimal contamination in the prep method or calibration procedure.
Control Samples	Verifies the accuracy of the method, including the prep procedure.
Duplicates	Verifies the precision of the instrument and/or method.
Spikes/Fortified Matrix	Determines sample matrix interferences, if any.
Standard	Verifies the validity of the calibration.

ACZ Qualifiers (Qual)

B	Analyte concentration detected at a value between MDL and PQL. The associated value is an estimated quantity.
H	Analysis exceeded method hold time. pH is a field test with an immediate hold time.
L	Target analyte response was below the laboratory defined negative threshold.
U	The material was analyzed for, but was not detected above the level of the associated value. The associated value is either the sample quantitation limit or the sample detection limit.

Method References

(1)	EPA 600/4-83-020. Methods for Chemical Analysis of Water and Wastes, March 1983.
(2)	EPA 600/R-93-100. Methods for the Determination of Inorganic Substances in Environmental Samples, August 1993.
(3)	EPA 600/R-94-111. Methods for the Determination of Metals in Environmental Samples - Supplement I, May 1994.
(4)	EPA SW-846. Test Methods for Evaluating Solid Waste.

Comments

(1)	QC results calculated from raw data. Results may vary slightly if the rounded values are used in the calculations.
(2)	Soil, Sludge, and Plant matrices for Inorganic analyses are reported on a dry weight basis.
(3)	Animal matrices for Inorganic analyses are reported on an "as received" basis.
(4)	An asterisk in the "XQ" column indicates there is an extended qualifier and/or certification qualifier associated with the result.
(5)	If the MDL equals the PQL or the MDL column is omitted, the PQL is the reporting limit.

Sample Receipt

SPF Water Engineering
Calico Monitoring Well Sampling

ACZ Project ID: L41826
Date Received: 12/16/2017 10:30
Received By:
Date Printed: 12/18/2017

Receipt Verification

	YES	NO	NA
1) Is a foreign soil permit included for applicable samples?			X
2) Is the Chain of Custody form or other directive shipping papers present?	X		
3) Does this project require special handling procedures such as CLP protocol?		X	
4) Are any samples NRC licensable material?			X
5) If samples are received past hold time, proceed with requested short hold time analyses?	X		
6) Is the Chain of Custody form complete and accurate?	X		
7) Were any changes made to the Chain of Custody form prior to ACZ receiving the samples?	X		

A change was made in the Report to Name. Copy of Report to Email. Sample ID Line 1. Relinquished By section prior to ACZ custody.

Samples/Containers

	YES	NO	NA
8) Are all containers intact and with no leaks?	X		
9) Are all labels on containers and are they intact and legible?	X		
10) Do the sample labels and Chain of Custody form match for Sample ID, Date, and Time?	X		
11) For preserved bottle types, was the pH checked and within limits? [1]	X		
12) Is there sufficient sample volume to perform all requested work?	X		
13) Is the custody seal intact on all containers?			X
14) Are samples that require zero headspace acceptable?			X
15) Are all sample containers appropriate for analytical requirements?	X		
16) Is there an Hg-1631 trip blank present?	X		
17) Is there a VOA trip blank present?			X
18) Were all samples received within hold time?	X		

NA indicates Not Applicable

1. INTRODUCTION

1.1. Background

A *Final Work Plan* (Plan) *for Grassy Mountain Monitoring Wells* prepared by SPF Water Engineering (SPF) dated November 28, 2016, was approved by the State of Oregon Technical Review Team (TRT) by letter dated January 6, 2017. The Plan described the location, construction, testing, and sampling of five proposed monitoring wells for Calico Resources USA Corp (Calico). These monitoring wells were proposed in the vicinity of the deposit for the purpose of aquifer characterization and to better understand the potential impacts of groundwater on mining operations, including potential dewatering requirements.

This well completion report describes the drilling, construction, testing, and water quality sampling from the deep downgradient well, referred to as GMW17-32. This report is intended to notify the TRT of initial testing and water quality results and re-development efforts.

1.2. Site Location

GMW17-32 is located in the SE ¼ of the NW ¼ of Section 8, Township 22 South, Range 44 East in Malheur County, Oregon. The well coordinates are 43.6724 decimal degrees latitude and -117.36157 decimal degrees longitude. The well is approximately 600 feet northwest of the deposit (Figure 1).

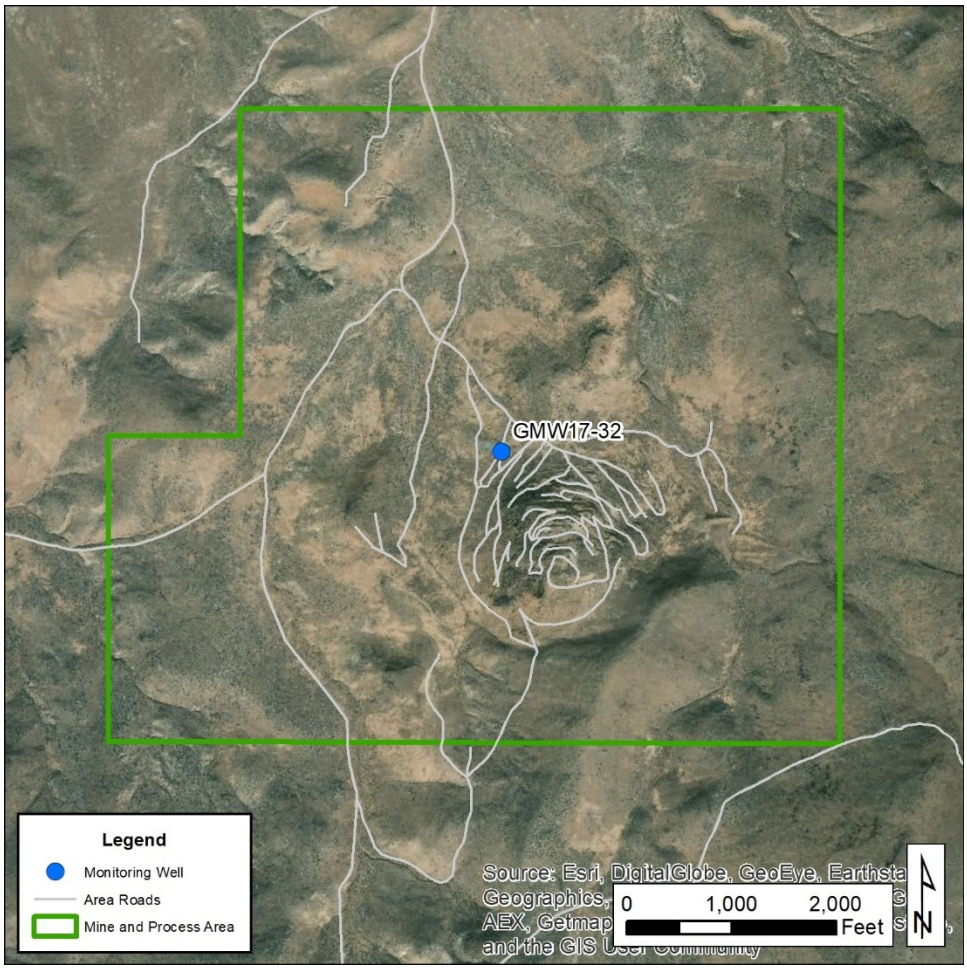

Figure 1. Vicinity map of well locations

2. DRILLING, CONSTRUCTION, AND DEVELOPMENT

2.1. Introduction

Well construction began on August 29, 2017 and was completed on November 30, 2017. The well was constructed using the air-rotary method of drilling by Down Right Drilling & Pump Inc. (Down Right), Oregon well driller's license number 1896. The well was constructed under start card number 1036039. The State of Oregon Monitoring Well Report is included in Attachment A.

2.2. Surface Casing Installation

As the first step in the well construction process, a nominal 10-inch borehole was drilled to 120 feet through the overburden (0 to 5 feet), siltstone/claystone and clay (5 to 20 feet), interbedded sandstone, siltstone, claystone, clay, and tuff (20 to 100 feet), and arkose/tuff (100 to 120 feet). The lithologic log is included in Attachment B. The 10-inch bore was

then reamed to a 16-inch bore from the surface to a depth of 118 feet for installation of a 12-inch surface casing.

A nominal 12-inch diameter mild steel casing with 0.250-inch wall thickness was installed from approximately 34 inches above ground surface to a depth of 118 feet. The annulus between the 12-inch casing and the 16-inch bore was sealed from 118 feet to ground surface with 79.2 ft^3 of Portland Type I/II neat cement grout pumped through a tremie pipe from the bottom up. This volume of cement is approximately 123% of the calculated volume needed for a 118-foot-long, 12.5-inch to 16-inch annulus.

2.3. Borehole Drilling

Following installation and sealing of the surface casing, a nominal 12-inch diameter bore was advanced from 118 to 1,004 feet by air-rotary drilling. Drilling encountered the following lithology as described on the lithologic log in Attachment B:

- arkose, tuff, and sinter to a depth of 175 feet
- clay to 195 feet
- siltstone, tuff, and minor sinter to 275 feet
- siltstone and mudstone to 325 feet
- siltstone and sinter to 375 feet
- siltstone and tuff to 410 feet
- arkose to 470 feet
- siltstone, mudstone, and clay to 515 feet
- arkose to 545 feet
- tuff, arkose, siltstone, and clay to 835 feet
- arkose with minor tuff and siltstone to 1,004 feet

The lithology is moderately to highly silicified from a depth of 150 feet to 550 feet with trace or weak silicification above and below this zone. The drilling was typically difficult, with layers of swelling clay, hard rock, and fractured pockets where circulation was lost.

Water was encountered at a depth of 235 feet, estimated to be approximately 25 gpm by air-lifting. The hole was drilled to the total depth of 1,004 feet by September 1, 2017. During drilling and associated air-lifting, there was no evidence of additional water below a depth of 235 feet. By September 5, the bore had caved back to 230 feet. Due to issues with hole instability, the driller, in consultation with SPF and Calico, determined that the best course of action was to install and seal 8-inch casing through the unstable borehole.

2.4. Installation of and Drilling Below 8-inch Casing

A nominal 8-inch diameter mild steel casing with 0.250-inch wall thickness was ultimately installed to a depth of 655 feet, with down-hole conditions preventing a deeper installation. Once the casing was installed, a nominal 8-inch diameter bore was drilled below the casing to a depth of 900 feet in an attempt to open the bore. No water was observed at the surface while drilling to 900 feet. At that depth unstable hole conditions required the drill pipe to be removed.

Once the drill pipe was removed, a camera was lowered down the well to assess bore conditions. The camera revealed that the hole had caved back to a depth of 681 feet. A large void was observed at that depth. In order to advance the bore and complete the well, it was decided that the void should be filled with cement to maintain circulation during drilling. A total of 243 ft^3 of Portland type I/II neat cement grout were pumped by tremie pipe into the bottom of the bore, where the top of the cement was tagged inside the 8-inch casing at a depth of 367 feet. Down Right then used a "dart" to push the cement down the 8-inch casing to a depth of 460 feet, with the intent of sealing the void and pushing cement upward into the annulus outside the 8-inch casing. This volume of cement is approximately 139% the calculated volume of the open bore/casing, annulus size, and annulus length mentioned above.

The annulus outside of the 8-inch casing was then sealed from a depth of 460 feet to ground surface with neat cement by pumping through a tremie pipe. A total of 451 ft^3 of Portland type I/II neat cement grout was pressure-grouted between the 12-inch annulus and 8-inch casing. The volume of grout pumped into the annulus during this process was 251% the calculated volume, indicating voiding and/or large amounts of cement loss to fractures.

After the seal was allowed to set up, drilling of a nominal 8-inch diameter bore was resumed to a depth of 900 feet. However, the hole ultimately caved back to a depth of 720 feet.

2.5. Casing and Screen Placement

The well was completed with a single string of nominal 5-inch diameter flush-joint schedule 80 PVC casing and screen. The casing was set from approximately 18 inches above ground surface to a depth of 678 feet, with screen (slot size 0.020-inch) set from a depth of 678 to 718 feet. The 5-inch casing was fitted with centralizers every 60 feet to maintain a consistent annular space inside the 8-inch casing.

2.6. Filter Pack

Filter pack (No. 10-20 Colorado Silica Sand) was placed in the annular space outside the 5-inch screen and casing from a depth of 670 to 719 feet. A filter pack seal consisting of No. 20-40 Colorado Silica Sand filter pack was placed from 668 to 670 feet to prevent cement intrusion into the underlying filter pack during seal placement. All filter pack was washed into place through flush-joint PVC tremie pipe.

2.7. Seal Placement

Following installation of the 5-inch PVC casing and screen and filter pack, tremie pipe was set to 668 feet (top of the filter pack seal) and 78 ft^3 of a bentonite-cement grout was pressure-grouted into the annulus between the 5-inch PVC casing, 8-inch steel casing, and 8-inch drilled cement plug in the 12-inch bore. The seal was placed from a depth of 287 feet to 668 feet. The grout volume required was approximately 114% of the calculated volume based on the annulus dimensions mentioned above. The bentonite-cement grout consisted of 3.75 pounds of bentonite (Wyo-Ben Groutwell DF) per 94-lb sack of Portland

type I/II neat cement with 7.8 gallons of water. The water and bentonite were mixed first, then the cement added to the slurry.

Sealing the 5-inch casing was performed in accordance with a Special Standards Request Form approved by the Oregon Water Resources Department (OWRD) by letter dated November 2, 2017. A copy of the letter is included with the Monitoring Well Report in Attachment A.

2.8. Well Head Assembly

The 12-inch surface casing extends approximately 34 inches above ground level. The surface casing serves as a protective well shelter for the PVC well casing. The surface casing is fitted with a locking cap to secure the well head. The 8-inch casing extends 1 foot above ground surface with visible cement in the annulus between the 8-inch and 12-inch casings. The top of the 5-inch PVC casing is approximately 18 inches above ground level and is fitted with a vented, removable sanitary well cap.

The OWRD well tag is permanently affixed to the 12-inch surface casing by means of a stainless steel band. A concrete pad (3 feet square) was poured around the well head shelter. Three protective bollards were placed around the well shelter.

Photographs of the well head assembly are provided in Attachment C.

2.9. As-Built Schematic

The as-built well construction schematic for the well is provided as Attachment D.

2.10. Well Development

After completion, GMW17-32 was bailed for 11 hours with a 3-inch bailer then development pumped at 0.5 gpm for 3.5 hours. The well produced some fine sand and silts during development. At the end of the development, the well was not producing sediment and the water only had a slight color.

3. TEST PUMPING AND WATER QUALITY

3.1. Well Testing

Well GMW17-32 was tested on December 11, 2017 using a 5-hp Grundfos S15-31 submersible pump. The pump was supplied by Down Right and set on 1-inch drop pipe at a depth of approximately 717 feet, 1 foot from the bottom of the well and 39 feet below the top of the screen interval. A 1.25-inch PVC sounding tube was installed to the top of the pump. After installation the pump was operated for a brief period of time to assess operation.

Prior to testing a water level pressure transducer was installed in the well to automatically record water levels at one-minute intervals. The pressure data was corrected for barometric pressure. The test pumping was supervised by Kurt Newbry, P.G. from SPF. Manual water level measurements were made by Kurt Newbry using a non-stretch well sounder. Due to low pumping rates, flow was measured with a 5-gallon bucket and stopwatch.

The static water level measured right before the start of test pumping was 648.33 feet below the measurement point (bmp). The measurement point was the top of the 1.25-inch sounding tube, 22.5 inches above the top of the 5-inch PVC casing, approximately 40 inches above ground surface. The well was finished being developed by pumping on December 8, 2017, at 19:00, allowing approximately 2.5 days of recovery prior to starting the test pumping. Given the slow recovery exhibited by this well, the well may still have been recovering from development when the test pumping began.

Well testing began at a pumping rate of 2.5 gpm, but after 17 minutes the water level was measured at 676.65 feet bmp (drawdown of 28.32 feet). In an attempt to prolong the test, the flow was reduced to 2 gpm. After pumping at 2 gpm for 67 minutes (84 minutes since test began), the water level was measured at 716.32 feet bmp (drawdown of 67.99 feet). The flow was reduced again to approximately 0.8 gpm. After 21 minutes of pumping at 0.8 gpm (105 minutes since test began), the water level reached the pump intake at a depth of 717.70 feet bmp and the pump was shut off to allow for recovery.

After 187 minutes of recovery, the water level was measured at 708.45 feet bmp. The pump was turned back on at 2 gpm and ran for 23 minutes to allow for water quality sampling.

An arithmetic time series plot showing well development, brief operation to test pump after installation, development pumping, test pumping, and recovery until December 28, 2017, is presented as Figure 2. Test pumping data are provided as Attachment E.

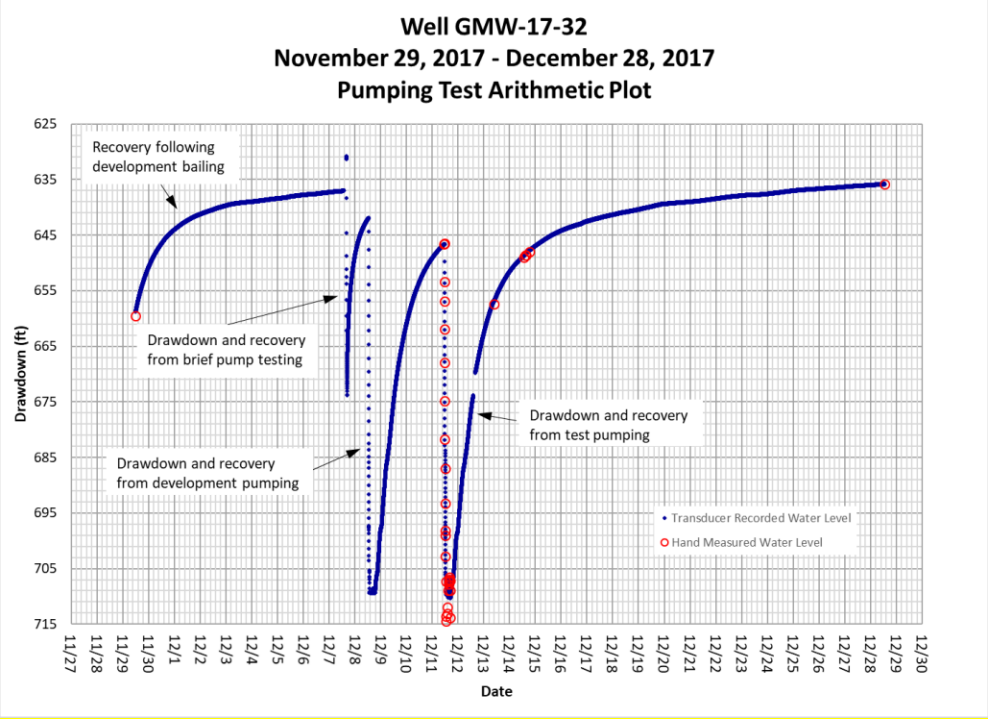

Figure 2. Pumping test arithmetic plot

3.2. Aquifer Characteristics

3.2.1. Casing Storage

The test pumping data was used to evaluate aquifer characteristics. In order to assess these characteristics, the volume of water actually pumped from the aquifer versus the water pumped from the casing (casing storage) needs to be determined. A total of 182 gallons were pumped from the well during the first part of the test before the water level reached the pump suction. The casing held approximately 66 gallons of water and the filter pack held an additional approximate 19 gallons of water, for a total casing storage estimate of 85 gallons. Therefore approximately 97 gallons of water were pumped from the formation. If this volume is divided by the initial test duration of 105 minutes, a pumping rate of 0.9 gpm is calculated.

3.2.2. Aquifer Transmissivity

A semi-log plot of the drawdown data is presented below as Figure 3. An aquifer transmissivity of approximately 5 gpd/ft (0.6 ft^2/d) is estimated using the drawdown data and a pumping rate of 0.9 gpm (water pumped from formation). Assuming a saturated aquifer thickness of 200 feet would result in an estimated hydraulic conductivity of 0.003 ft/d. If only the screened interval contributed flow to the well with a saturated thickness of 40 feet, the assumed hydraulic conductivity would be 0.015 ft/d.

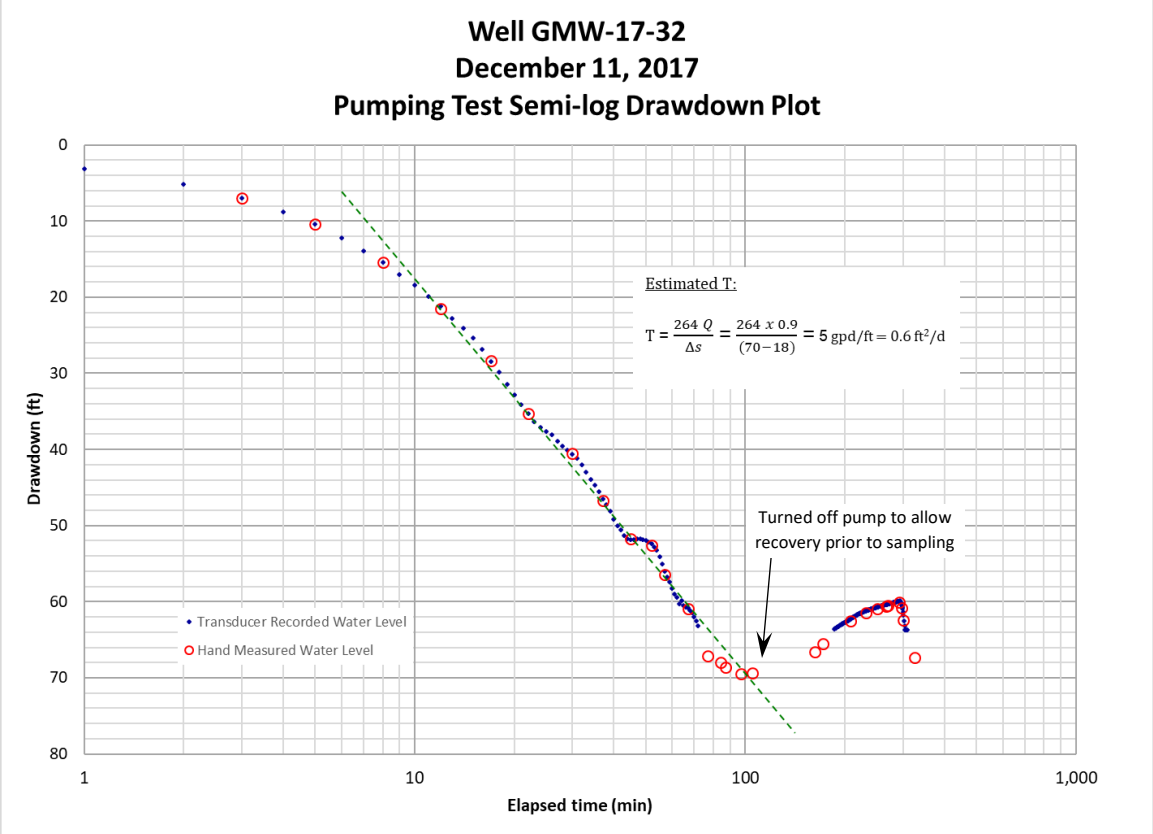

Figure 3. Pumping test semi-log drawdown plot

A semi-log plot of the recovery data collected following the test pumping until June 26, 2018, is presented below as Figure 4. An aquifer transmissivity of approximately 0.6 gpd/ft (0.08 ft^2/d) is estimated using the recovery data and an average pumping rate of 0.9 gpm. Assuming a saturated aquifer thickness of 200 feet would result in an estimated hydraulic conductivity of 0.0004 ft/d. If only the screened interval contributed flow to the well with a saturated thickness of 40 feet, the assumed hydraulic conductivity would be 0.002 ft/d.

The estimated aquifer transmissivity ranges from 0.6 to 5 gpd/ft, while the hydraulic conductivity is estimated to range from 0.002 to 0.015 ft/d assuming only the screened interval is contributing flow to the well. The transmissivity and conductivity values are considered to be very low.

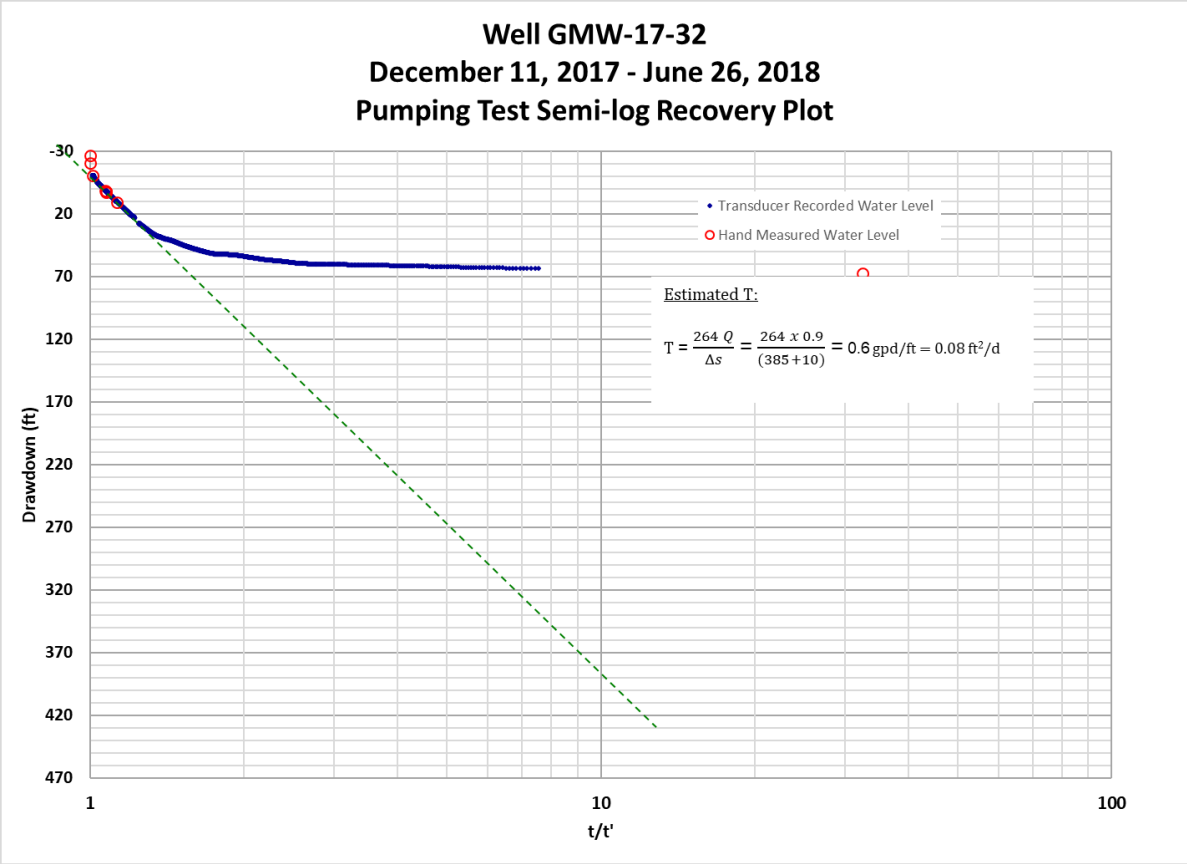

Figure 4. Pumping test semi-log drawdown plot

3.3. Response in Nearby Wells

During the testing of GMW17-32, water levels were measured in nearby wells using water level transducers and manual measurements with a non-stretch well sounder. Pressure transducers were installed in wells 59762, GMW17-33 (shallow pair to GMW17-32), GW-3, 26-92-915, BLM, PW-1, GW-1, 57-10, 59761, 59772, GW-2, and GW-4. A map showing

these wells in proximity to GMW17-32 is included as Figure 5. Plots showing water levels in each of these wells are provided in Attachment F.

The water level plots show that there was no measurable response observed in any of the wells as a result of testing GMW17-32.

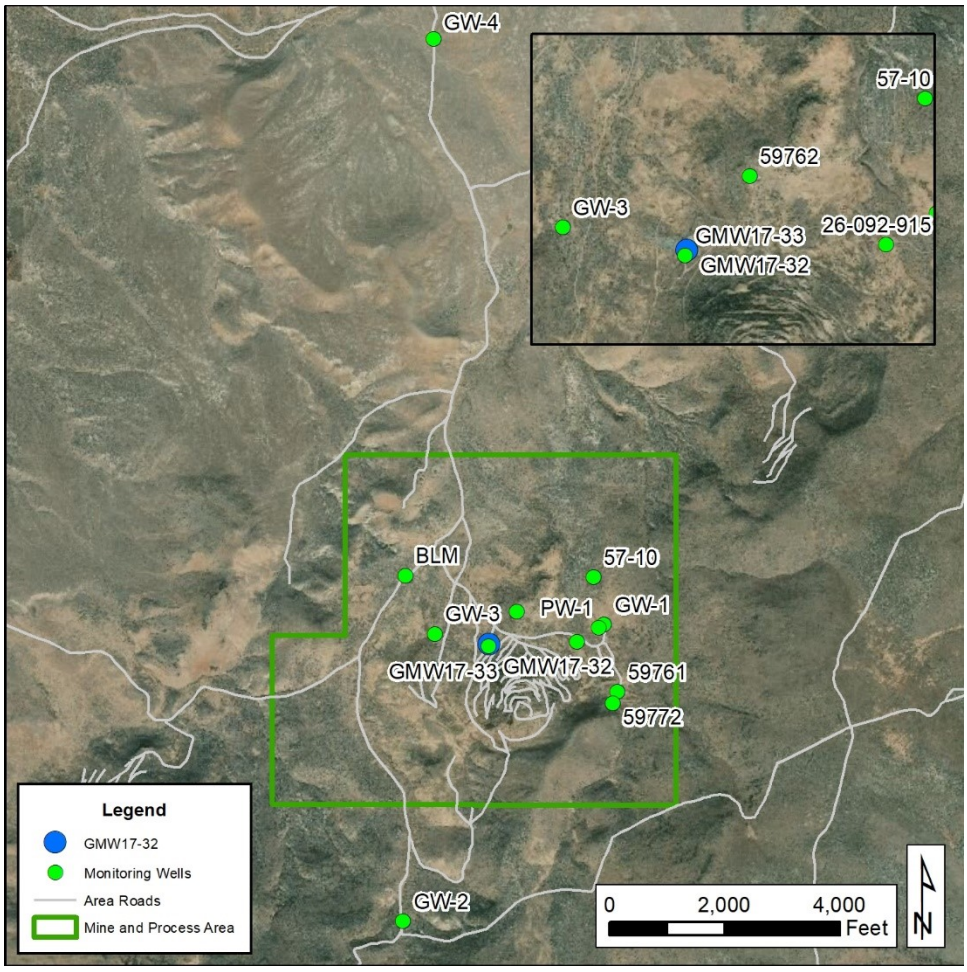

Figure 5. Monitoring well map

3.4. Water Level Recovery

The static water level was measured at a depth of 635.82 feet below the top of the 5-inch casing (btoc) on December 28, 2017, 17 days after the end of the test pumping. The static water level was measured 10 feet higher at a depth of 625.82 feet btoc on March 7, 2018, 86 days after the end of test pumping. The static water level was measured nearly 6 feet higher at a depth of 619.84 feet btoc on June 26, 2018, 197 days after the end of test pumping. A plot of the water level recovery data is presented below as Figure 6.

These measurements indicate that the water level in the well is still recovering and has not reached steady-state conditions. The true piezometric surface is not known at this time. The very slow recovery observed in this well provides more evidence of an extremely low hydraulic conductivity.

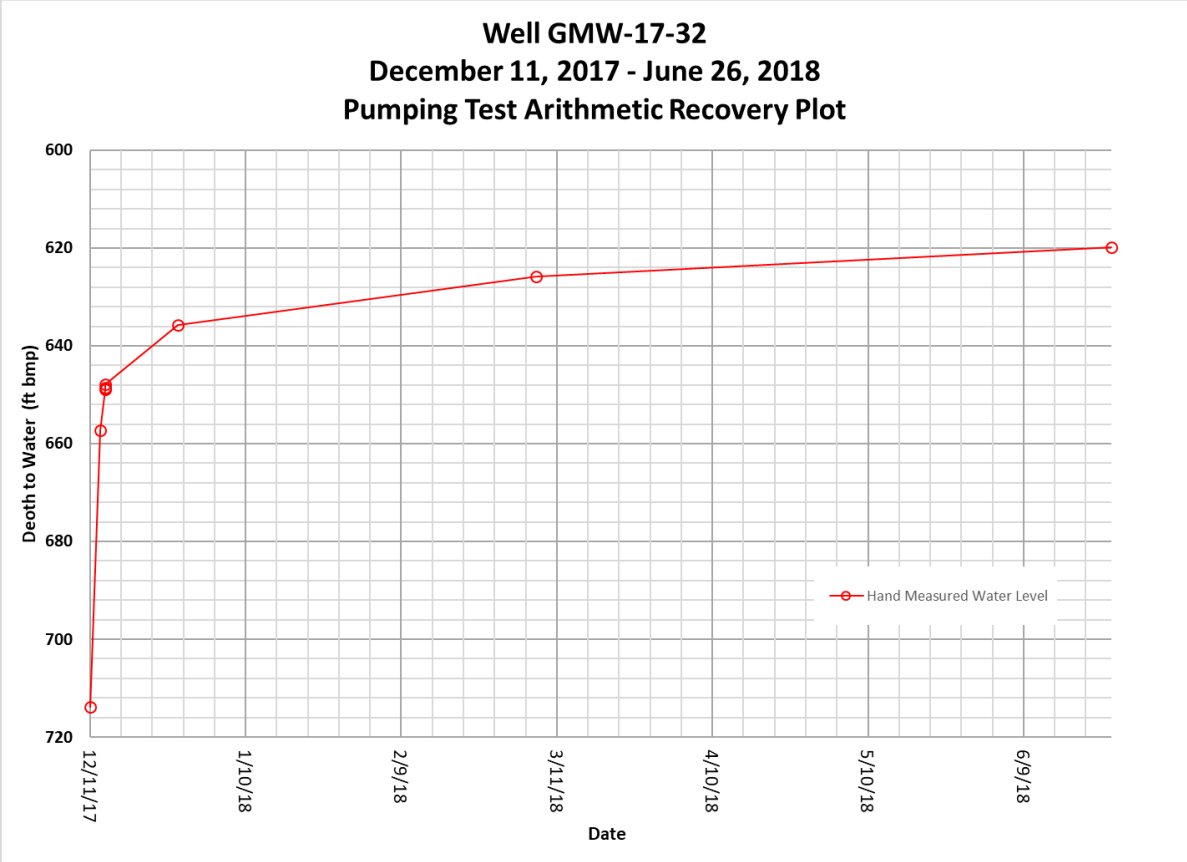

Figure 6. Pumping test arithmetic recovery plot

3.5. Initial Water Quality

3.5.1. Field Water Quality

Field water quality were collected throughout the test pumping. Results are summarized in Table 1 below. The pH measured throughout the test pumping is unusually high, with a value of 11.97 measured right before sample collection. The laboratory reported a pH of 11.3, slightly lower than the pH measured in the field. A pH of around 8 is expected based on the nearby deep well 59762. The conductivity values are also higher than expected when compared to well 59762. The high pH and conductivity values are attributed to inadequate development, with these water quality parameters likely affected by drill cuttings or cement.

Table 1. Field water quality data

Time	pH (S.U.)	EC (µS/cm)	SC (µS/cm @ 25°C)	Temp. (°C)	DO (mg/L)	Notes
11:42	11.93	1745	1930	19.1	1.69	water cloudy
11:52	11.98	1819	1952	21.4	1.05	
12:07	12	1882	1990	22.1	1.65	
12:37	12.03	2048	2149	22.5	0.96	
12:54	11.96	1858	1950	22	0.68	water very cloudy, yellowish brown
12:57	11.98	1889	1995	21.7	0.69	
16:31	11.95	1880	1990	20	0.65	water clearing up, slightly cloudy
16:32	11.97	1887	2095	22	0.69	water slightly cloudy

3.5.2. Laboratory Water Quality

Water quality samples were collected by Kurt Newbry of SPF near the end of the test pumping on December 11, 2017 at 16:32. Samples were taken from a sample tap in the discharge piping while pumping at approximately 2 gpm. The water had a minor amount of color prior to sampling. Water quality sampling procedures and quality assurance/quality control were conducted per the Environmental Baseline Study Work Plans (Work Plans) for the Grassy Mountain Project dated May 17, 2017.

A total of 200 gallons was pumped from the well prior to sampling, equal to three casing volumes of water. This volume removed only accounts for water removed during testing, and does not include water removed from well during bailing and development pumping. Samples were collected for the water quality analytes listed in Table 15 of Section 3.4.4.2.11 of the Work Plans, as amended to include uranium, replace nitrate and nitrite sampling with combined nitrate+nitrite, and remove inorganic arsenic. The samples were shipped to ACZ Laboratories (ACZ) in Steamboat Springs, Colorado on December 12, 2017. The samples were received by ACZ at a temperature of 3.9°C, below the upper limit of 6°C. The field form and laboratory report are provided in Attachment G.

3.5.3. Water Quality Comparison to Drinking Water Standards

Water quality analytical results were compared to Environmental Protection Agency (EPA) primary and secondary drinking water standards. Primary drinking water standards are legally enforceable standards meant to protect public health. The enforceable standards are referred to as maximum contaminant levels (MCLs). Secondary drinking water standards are non-enforceable water quality standards meant to address aesthetic concerns with drinking water, including taste, color, and odor. Secondary standards do not present a public health risk.

The water quality parameters from GMW17-32 exceeding primary or secondary drinking water standards are summarized in Table 2. A total of four analytes exceed their respective MCL; both the total and dissolved concentrations of antimony and arsenic exceeded the MCL.

Nitrate+nitrite was used as a substitute for nitrate and nitrite in this study, which does not have an MCL. However, the water did not have a nitrate+nitrite level exceeding the MCL for nitrite (1 mg/L). Nitrate has a higher MCL of 10 mg/L.

Table 2. Water Quality Results Exceeding Drinking Water Standards

Parameter	MCL (mg/L)	12-11-17 Sample Result (mg/L)[1]
Aluminum, dissolved	0.05	0.25
Aluminum, total	0.05	4.78
Antimony, dissolved	0.006	0.115
Antimony, total	0.006	0.0666
Arsenic, dissolved	0.01	0.0588
Arsenic, total	0.01	0.116
Chromium, total	0.1	0.3
Iron, total	0.3	35.5
Lead, total	0.015	0.0204
Manganese, total	0.05	0.206
Residue, Filterable (TDS) @180C	500	920
Sulfate	250	381

1- values in red are analytes that exceeded primary drinking water standards

3.5.4. Major Ion Geochemistry

Geochemical characteristics of the groundwater from GMW17-32 were evaluated using Piper diagrams (also known as Trilinear diagrams) and Stiff diagrams, with major ions expressed as meq/L. These diagrams are useful for evaluating the geochemical signature of the water, to illustrate general differences in water chemistry using major ions, and to group waters with similar chemical signature into identifiable groups.

The Stiff diagram for GMW17-32 is presented as Figure 7. The Stiff diagram identifies the groundwater as having a sodium-potassium sulfate (Na/K-SO4) water quality signature. For comparison, the nearby deep well 59762 has the same signature.

The Piper diagram for the groundwater quality data from GMW17-32 and the 3rd Quarter 2014 data from all other wells is presented as Figure 8. The Piper diagram also shows a sodium-potassium sulfate (Na/K-SO4) water quality signature for GMW17-32. Well 59762 shows a similar signature.

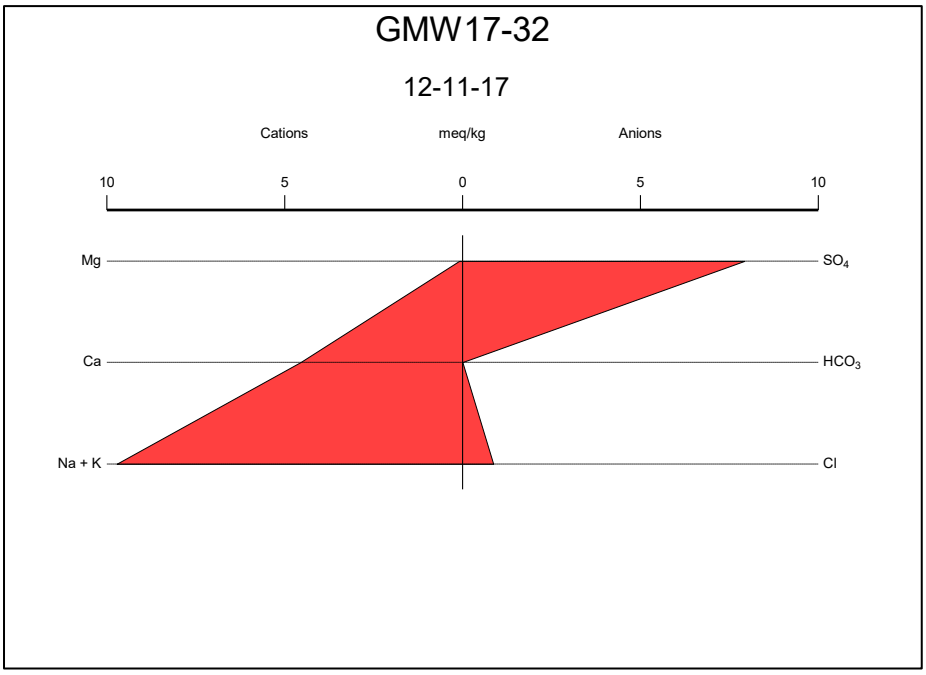

Figure 7. Stiff diagram for GMW17-32

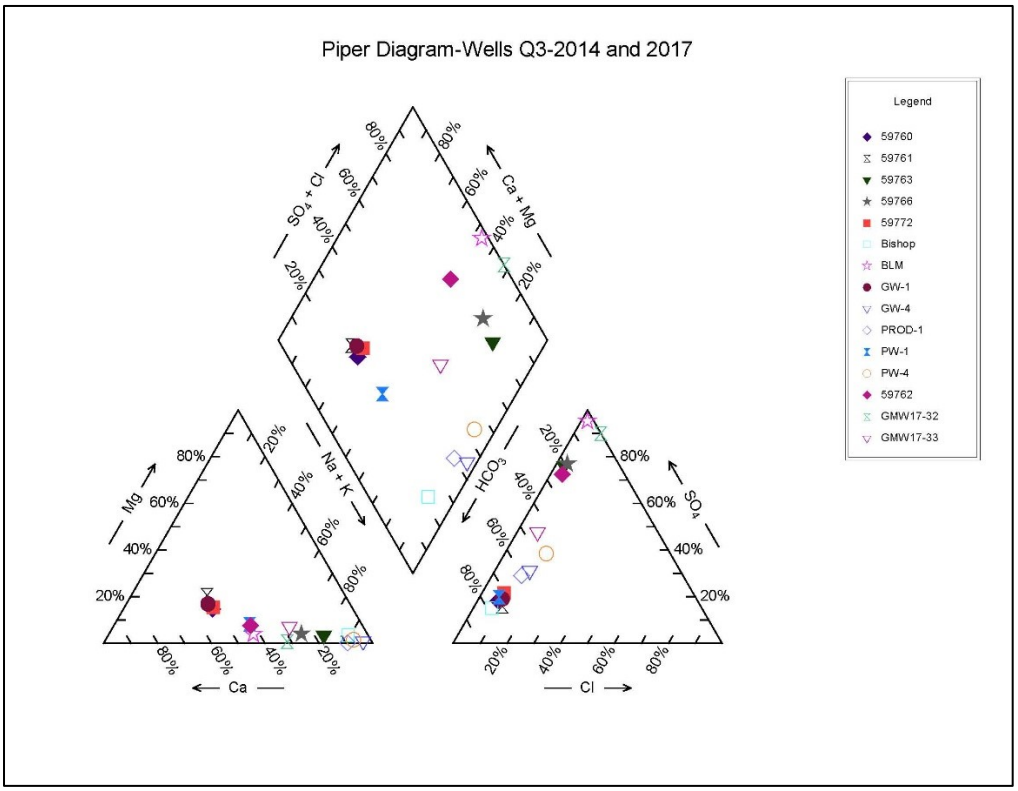

Figure 8. Piper Diagram

3.6. Well Re-development and Sampling

3.6.1. Re-development

The high pH and conductivity, along with minor turbidity observed during the initial sample collection from GMW17-32 suggests inadequate development of the well. Therefore, the well was re-developed by re-installing the test pump and pumping on the well until the water reached the pump suction. This effort occurred on six different occasions between July 18 and July 25, 2018. A total of approximately six casing volumes (approximately 400 gallons) were removed from the well.

3.6.2. Field Water Quality

Field water quality were collected following well re-development pumping on July 25, 2018. Results are summarized in Table 3 below. The pH measured in the field prior to sampling was 10.74, lower than the 11.97 measured prior to the first sample collection. The laboratory reported a pH of 10.3, slightly lower than the pH measured in the field.

The specific conductance was also considerably lower, 1209 µS/cm at 25°C versus 2095 µS/cm at 25°C. During sampling the water was clear, but had a cloudy red appearance prior to and after sampling. The lower pH and conductivity values, along with the water clarity, suggests that the re-development has had a positive effect on water quality.

Table 3. Field water quality data during re-development

Time	pH (S.U.)	EC (µS/cm)	SC (µS/cm @ 25°C)	Temp. (°C)	DO (mg/L)	Notes
11:18	11.44	1134	1390	15.3	1.45	water cloudy red
11:27	11.22	1126	1270	18.9	0.51	water cloudy red
11:36	10.74	1047	1118	21.7	2.76	water clear
11:57	10.78	1126	1192	22.2	3.34	water slightly cloudy
12:00	11.12	1192	1258	22.2	3.60	water cloudy red
12:04	11.06	1145	1209	22.3	2.62	water cloudy red

1.1.1. Laboratory Water Quality

Water quality samples were collected by Kurt Newbry of SPF following well re-development on July 25, 2018 at 11:36. Samples were taken from a sample tap in the discharge piping while pumping at approximately 2.6 gpm. Samples were collected for the same parameters as the initial sampling. The sample were shipped to ACZ Laboratories (ACZ) in Steamboat Springs, Colorado on July 25, 2018. The samples were received by ACZ at a temperature of 5.7°C, below the upper limit of 6°C. The field form and laboratory report are provided in Attachment H.

3.6.3. Water Quality Comparison to Drinking Water Standards

Water quality analytical results from the re-sampling were compared to primary and secondary drinking water standards. The water quality parameters from re-sampling GMW17-32 that exceeded primary or secondary drinking water standards are summarized in Table 4. A total of two analytes exceed their respective MCL, antimony and arsenic. Both the total and dissolved concentrations of antimony and arsenic exceeded the MCL.

Table 4. Water Quality Re-Sampling Results Exceeding Drinking Water Standards

Parameter	MCL (mg/L)	7-25-18 Sample Result (mg/L)[1]
Aluminum, total	0.05	0.09
Antimony, dissolved	0.006	0.0939
Antimony, total	0.006	0.0876
Arsenic, dissolved	0.01	0.0871
Arsenic, total	0.01	0.0881
Iron, total	0.3	0.34
Residue, Filterable (TDS) @180C	500	768
Sulfate	250	417

1- values in red are analytes that exceeded primary drinking water standards

3.6.4. Major Ion Geochemistry

Geochemical characteristics of the re-sampled groundwater from GMW17-32 were evaluated using Piper diagrams and Stiff diagrams. The Stiff diagram for the re-sampled GMW17-32 is presented as Figure 9.

The Stiff diagram identifies the groundwater as having a sodium-potassium sulfate (Na/K-SO4) water quality signature, the same as the original samples.

The Piper diagram for the original and re-sampled groundwater quality data from GMW17-32 and the 3rd Quarter 2014 data from all other wells is presented as Figure 10. The Piper diagram also shows a sodium-potassium sulfate (Na/K-SO4) water quality signature for the original sample and re-sample from GMW17-32.

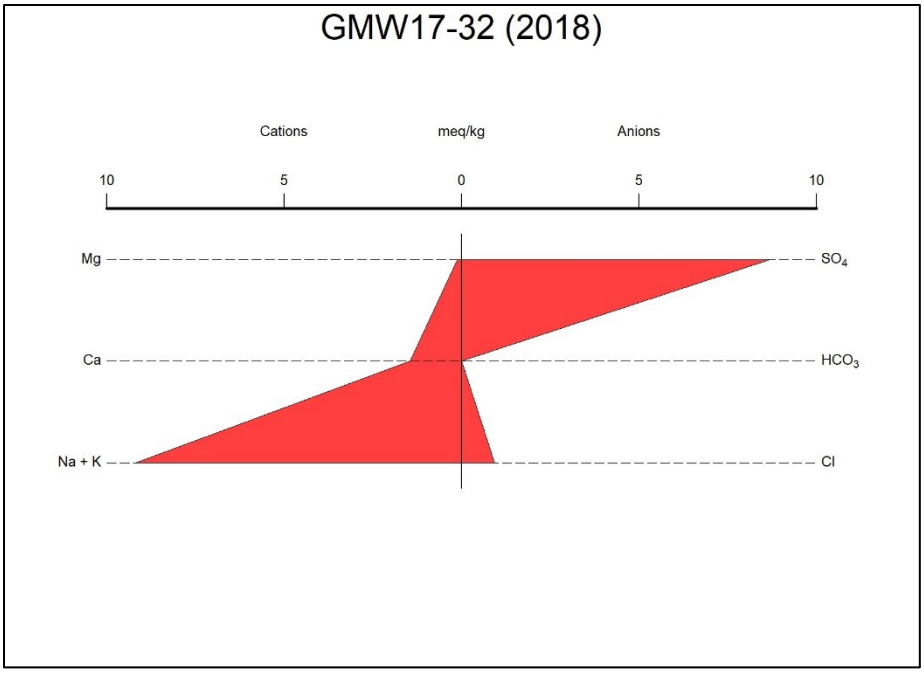

Figure 9. Stiff diagram for GMW17-32 re-samples

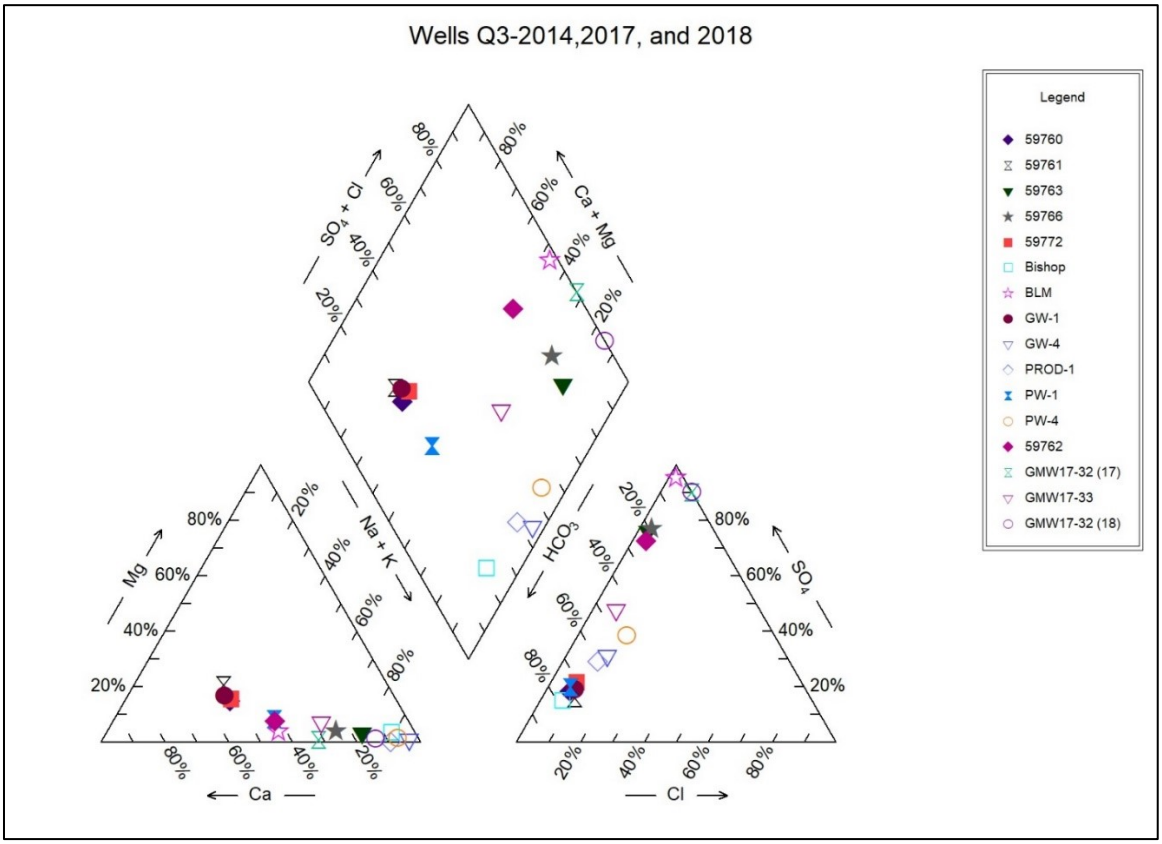

Figure 10. Piper Diagram with re-sampled GMW17-32

3.7. Comparison of Water Quality Results

The water quality data from the initial sampling can be compared to the data from the re-sampling to assess variability. An analysis of the data revealed that 47 out of a total of 83 parameters are significantly different between the two sampling events. Samples are considered to be significantly different if two conditions apply: (1) the original and/or re-sampling results are greater than five times the laboratory minimum detection limit (MDL) and (2) the percent difference between the results is equal to or greater than 20%. The number of significantly different parameters suggests that re-development efforts affected the water quality obtained from the well. The number might also reflect natural variability.

4. CONCLUSIONS

1. The deep downgradient well GMW17-32 was successfully completed per the *Final Work Plan for Grassy Mountain Monitoring Wells.*

2. The 12-inch diameter well bore was drilled to a total depth of 1,004 feet. The bore encountered silicified siltstone and mudstone, along with arkose, clay, sinter, and tuff. Water was encountered at a depth of 235 feet, estimated to be approximately 25 gpm by air-lift pumping. There was no evidence of additional water below this depth.

3. Drilling was difficult due to the hard, silicified lithology, with layers of swelling clay and zones of fractured rock that resulted in loss of circulation and sloughing conditions.

4. An unstable bore required the installation of an 8-inch steel casing to a depth of 655 feet, sealed to ground surface. A nominal 8-inch diameter open hole was re-drilled to 900 feet.

5. The well was completed with a single string of nominal 5-inch diameter flush-joint schedule 80 PVC casing and screen. The screen was set from a depth of 678 to 718 feet. Screen placement was shallower than planned due to caving hole conditions. Filter pack was placed around the screens. The PVC casing was sealed from the top of the filter pack (688 feet) to a depth of 287 feet.

6. The well was initially developed by bailing and pumping with the test pump.

7. The well was test pumped for a total of just over 2 hours. The pumping rate started out at 2.5 gpm, but had to be ultimately valved back to less than 1 gpm to enable three casing volumes to be pumped out before sampling.

8. Test pumping suggests an aquifer transmissivity of between 0.6 and 5 gpd/ft and a hydraulic conductivity ranging from 0.002 to 0.015 ft/d. The transmissivity and conductivity values are considered to be very low.

9. No water level response was observed in any nearby monitoring wells during testing of the well.

10. The water level in the well is still recovering from testing and has not yet reached steady-state conditions. The true piezometric surface is not known at this time.

11. High pH and conductivity values measured during test pumping along with the appearance of turbid water suggested that the well was not adequately developed after construction.

12. Initial sampling had four analytes exceed their respective MCL, including antimony, arsenic, chromium, and lead; both the total and dissolved concentrations of antimony and arsenic exceeded the MCL.

13. The groundwater has a sodium-potassium sulfate (Na/K-SO4) water quality signature.

14. The well was re-developed by re-installing the test pump and pumping the well until the water reached the pump suction six times during a seven-day period.

15. After re-development, the water pumped from the well had a lower pH and conductivity, which along with better water clarity suggests that the re-development has had a positive effect on water quality. The pH was still considered to be above normal.

16. Following re-development, a total of two analytes exceed their respective MCL, antimony and arsenic. Both the total and dissolved concentrations of antimony and arsenic exceeded the MCL.

17. The re-sampled groundwater has a sodium-potassium sulfate (Na/K-SO4) water quality signature, same as the original sample.

18. Over half of the parameters sampled for were significantly different before and after re-development, which suggests that re-development efforts affected the water quality obtained from the well.

5. DISCUSSION

The re-development pumping of GMW17-32 appears to have removed residual cuttings, sediment, and other materials from the screen and filter pack. Despite the apparent improvement, the water quality produced from the well is still probably affected by inadequate development. The well's usefulness as a water quality sampling location is therefore currently limited, but it can serve as a long-term water-level monitoring location.

Aquifer characteristics make development of GMW17-32 very challenging. The aquifer does not yield adequate water to completely flush residual drill cuttings or fluids from the filter pack and nearby formation. Similar poor well production has also been observed in the nearby deep well 59762. So, while water quality results may not be representative of the formation water, the construction and testing of GMW17-32 indicates that the silicified siltstone and sandstone, while saturated, has very limited water-bearing potential and a very low hydraulic conductivity. In fact, the water-bearing strata should not be considered an aquifer in the sense of a sustainable water-bearing lithology. The water that is present

in the rock is quickly dewatered, with a very slow recharge and recovery. The usefulness of water quality data from this deep saturated zone is therefore questionable. The most recent static water level from June 2018 was measured at a depth of about 620 feet, equal to an elevation of 3,080 feet. The water level in the well is still recovering, with a final water surface elevation expected to be at or below the anticipated bottom of the mine at 3,100 feet.

There is no evidence to suggest a well drilled in the vicinity of the deposit will yield more water. The nearby well 59762 produced a similar yield as GMW17-32 when tested. The recently completed upgradient deep well was dry.

An attempt could be made to perform more development on the well to obtain more reliable water quality samples. There appears to be two options for additional well development.

- The first option is additional pumping, but this approach has had limited success and is very time consuming as it is limited by low well capacity. It could take weeks to months of pumping to adequately develop the well.

- The other option is to flush the well with water from another source in an attempt to clear the screen and filter pack of residual cuttings and sediment. The recommended approach would be to inject one casing volume of water. Water would be introduced and monitored until pre-injection water levels are obtained, indicating that water was forced through the screen and into the filter pack. Then two casing would be pumped out, one volume for the water originally in the well and one volume for the introduced water. This process would be repeated until a water pH of around 8 is achieved. The goal would be to introduce enough water to clear the screen and filter pack but limit the volume of water entering the formation since this water would have to be pumped out to obtain a water sample representative of the formation water. If and when a normal pH is measured, an additional 3 casing volumes would be pumped from the well to ensure that whatever volume of water was introduced would also be pumped out. The volume of water introduced into the well would be carefully monitored.

  The proposed source of injection water is Prod-1. This well is capable of providing enough water to conduct this development. There is also seven quarters of sampling data from this well so its water quality is well understood if needed to assess if all the introduced water has been removed from the well.

Although the additional efforts described above could be put towards developing this well, the well may better be suited to function strictly as a water level monitoring location. Even if development were able to achieve water quality samples representative of the water-bearing strata, the usefulness of this information is questionable given the limited hydraulic connectivity of the strata, low hydraulic conductivity, and poor recharge. However, construction and testing of the well has provided very useful information describing the hydrogeological characteristics of this deep saturated zone.

(unbonded) Monitor Well Constructor Certification

I certify that the work I performed on the construction, deepening, alteration, or abandonment of this well is in compliance with Oregon monitoring well construction standards. Materials used and information reported above are true to the best of my knowledge and belief.

License Number 1896 Date 12/14/2017
Password : (if filing electronically) _____
Signed TONY HACKETT (E-filed)

(bonded) Monitor Well Constructor Certification

I accept responsibility for the construction, deepening, alteration, or abandonment work performed on this well during the construction dates reported above. All work performed during this time is in compliance with Oregon monitoring well construction standards. This report is true to the best of my knowledge and belief.

License Number 1899 Date 12/14/2017

FINAL ORDER

Dear Mr. Kingrey:

The Special Standards Request Form you submitted for owner: Calico Resources USA Corp., Start Card number 1036039 is hereby approved for the following: You may construct this monitoring well as outlined in your completed Special Standards Request Form dated October 24, 2017. You may seal the 5 inch diameter schedule 80 pvc casing inside the 8 inch diameter steel casing as requested. A stipulation for this request approval is that the 5 inch casing shall have centralizers at a minimum of 60 foot intervals and the 5 inch casing shall be sealed with cement grout from the top of the filter pack seal upward 300 feet. The reported sloughing of the borehole below 720 feet may be left in place at this time. This Special Standards Request is a modification of the Special Standards Request approval letter dated September 29, 2017. A copy of your Special Standards Request Form is enclosed.

Verbal approval of this Special Standards Request was provided on October 24, 2017.

The Well Construction Standards serve to protect ground water resources. By approving and issuing this special construction standard the Oregon Water Resources Department is not representing that a well constructed in accordance with this condition will maintain structural integrity or that it meets engineering standards. The well constructor/or landowner is responsible for ensuring that a well is constructed in a manner that protects ground water resources as required under Oregon Administrative Rules 690-200 through 690-240.

If you have any questions concerning this letter, I may be contacted at (503) 986-0852, or by e-mail at Joel.W.Jeffery@oregon.gov.

Sincerely,

Joel Jeffery, Coordinator
Well Construction Program
Well Construction and Compliance Section

enclosure

cc: Bob Maynard, East Region Well Inspector
File

This is a final order in other than contested case. This order is subject to judicial review under ORS 183.484. Any petition for judicial review must be filed within the 60 day time period specified by ORS 183.484(2). Pursuant to ORS 536.075 and OAR 137-004-0080 you may either petition for judicial review or petition the Director for reconsideration of this order. A petition for reconsideration may be granted or denied by the Director, and if no action is taken within 60 days following the date the petition was filed, the petition shall be deemed denied.

Test Pumping Data

Grassy Mtn. GMW-17-32 Pumping Test
12/11/2017

Tested by Down Right Drilling & Pump. Supervised by Kurt Newbry (SPF Water Engineering).

Pump type: 5-HP submersible Grundfos. Pump intake set at ~717 feet.

Flow measured with 5-gallon bucket. 1-inch discharge pipe.

Water level measured with non-stretch 800-foot Waterline well sounder.

Measurement point: end of 1.25-inch PVC sounding tube at top of casing

Water Quality Results

ACZ Laboratories, Inc.
2773 Downhill Drive Steamboat Springs, CO 80487 (800) 334-5493

Analytical Report

January 15, 2018

Report to:
Jason Thompson
SPF Water Engineering
300 E. Mallard Drive, Suite 350

Boise, ID 83706

cc: Kurt Newbry

Bill to:
Jason Thompson
SPF Water Engineering
300 E Mallard Drive
Suite 350
Boise, ID 83706

Project ID: Calico Monitoring Well Samplin
ACZ Project ID: L41754

Jason Thompson:

Enclosed are the analytical results for sample(s) submitted to ACZ Laboratories, Inc. (ACZ) on December 13, 2017. This project has been assigned to ACZ's project number, L41754. Please reference this number in all future inquiries.

All analyses were performed according to ACZ's Quality Assurance Plan. The enclosed results relate only to the samples received under L41754. Each section of this report has been reviewed and approved by the appropriate Laboratory Supervisor, or a qualified substitute.

Except as noted, the test results for the methods and parameters listed on ACZ's current NELAC certificate letter (#ACZ) meet all requirements of NELAC.

This report shall be used or copied only in its entirety. ACZ is not responsible for the consequences arising from the use of a partial report.

All samples and sub-samples associated with this project will be disposed of after February 14, 2018. If the samples are determined to be hazardous, additional charges apply for disposal (typically $11/sample). If you would like the samples to be held longer than ACZ's stated policy or to be returned, please contact your Project Manager or Customer Service Representative for further details and associated costs. ACZ retains analytical raw data reports for ten years.

If you have any questions or other needs, please contact your Project Manager.

Max Janicek has reviewed and approved this report.

Metals Analysis

Parameter	EPA Method	Dilution	Result	Qual	XQ	Units	MDL	PQL	Date	Analyst
Mercury, total	M1631, Atomic Fluorescence	1		U		ng/L	0.2	0.5	12/21/17 13:29	mfm

Report Header Explanations

Batch	A distinct set of samples analyzed at a specific time
Found	Value of the QC Type of interest
Limit	Upper limit for RPD, in %.
Lower	Lower Recovery Limit, in % (except for LCSS, mg/Kg)
MDL	Method Detection Limit. Same as Minimum Reporting Limit unless omitted or equal to the PQL (see comment #5). Allows for instrument and annual fluctuations.
PCN/SCN	A number assigned to reagents/standards to trace to the manufacturer's certificate of analysis
PQL	Practical Quantitation Limit. Synonymous with the EPA term "minimum level".
QC	True Value of the Control Sample or the amount added to the Spike
Rec	Recovered amount of the true value or spike added, in % (except for LCSS, mg/Kg)
RPD	Relative Percent Difference, calculation used for Duplicate QC Types
Upper	Upper Recovery Limit, in % (except for LCSS, mg/Kg)
Sample	Value of the Sample of interest

QC Sample Types

AS	Analytical Spike (Post Digestion)	*LCSWD*	Laboratory Control Sample - Water Duplicate
ASD	Analytical Spike (Post Digestion) Duplicate	*LFB*	Laboratory Fortified Blank
CCB	Continuing Calibration Blank	*LFM*	Laboratory Fortified Matrix
CCV	Continuing Calibration Verification standard	*LFMD*	Laboratory Fortified Matrix Duplicate
DUP	Sample Duplicate	*LRB*	Laboratory Reagent Blank
ICB	Initial Calibration Blank	*MS*	Matrix Spike
ICV	Initial Calibration Verification standard	*MSD*	Matrix Spike Duplicate
ICSAB	Inter-element Correction Standard - A plus B solutions	*PBS*	Prep Blank - Soil
LCSS	Laboratory Control Sample - Soil	*PBW*	Prep Blank - Water
LCSSD	Laboratory Control Sample - Soil Duplicate	*PQV*	Practical Quantitation Verification standard
LCSW	Laboratory Control Sample - Water	*SDL*	Serial Dilution

QC Sample Type Explanations

Blanks	Verifies that there is no or minimal contamination in the prep method or calibration procedure.
Control Samples	Verifies the accuracy of the method, including the prep procedure.
Duplicates	Verifies the precision of the instrument and/or method.
Spikes/Fortified Matrix	Determines sample matrix interferences, if any.
Standard	Verifies the validity of the calibration.

ACZ Qualifiers (Qual)

B	Analyte concentration detected at a value between MDL and PQL. The associated value is an estimated quantity.
H	Analysis exceeded method hold time. pH is a field test with an immediate hold time.
L	Target analyte response was below the laboratory defined negative threshold.
U	The material was analyzed for, but was not detected above the level of the associated value. The associated value is either the sample quantitation limit or the sample detection limit.

Method References

(2) EPA 600/R-93-100. Methods for the Determination of Inorganic Substances in Environmental Samples, August 1993.
(3) EPA 600/R-94-111. Methods for the Determination of Metals in Environmental Samples - Supplement I, May 1994.
(4) EPA SW-846. Test Methods for Evaluating Solid Waste.
(5) Standard Methods for the Examination of Water and Wastewater.

Comments

(1) QC results calculated from raw data. Results may vary slightly if the rounded values are used in the calculations.
(2) Soil, Sludge, and Plant matrices for Inorganic analyses are reported on a dry weight basis.
(3) Animal matrices for Inorganic analyses are reported on an "as received" basis.
(4) An asterisk in the "XQ" column indicates there is an extended qualifier and/or certification qualifier associated with the result.
(5) If the MDL equals the PQL or the MDL column is omitted, the PQL is the reporting limit.

For a complete list of ACZ's Extended Qualifiers, please click: http://www.acz.com/public/extquallist.pdf

SPF Water Engineering ACZ Project ID: ***L41754***

ACZ ID	WORKNUM	PARAMETER	METHOD	QUAL	DESCRIPTION
L41754-01	WG439029	Antimony, total	M200.8 ICP-MS	M3	The spike recovery value is unusable since the analyte concentration in the sample is disproportionate to the spike level. The recovery of the associated control sample (LCS or LFB) was acceptable.
	WG438849	Beryllium, dissolved	M200.8 ICP-MS	VC	CCV recovery was above the acceptance limits. Target analyte was not detected in the sample [< MDL].
	WG438878	Cyanide, total	M335.4 - Colorimetric w/ distillation	RA	Relative Percent Difference (RPD) was not used for data validation because the concentration of the duplicated sample is too low for accurate evaluation (< 10x MDL).
	WG438693	Cyanide, WAD	SM4500-CN I,E-Colorimetric w/ distillation	RA	Relative Percent Difference (RPD) was not used for data validation because the concentration of the duplicated sample is too low for accurate evaluation (< 10x MDL).
	WG438601	Fluoride	M300.0 - Ion Chromatography	DC	Sample required dilution. Non-target analyte exceeded calibration range.
			M300.0 - Ion Chromatography	RA	Relative Percent Difference (RPD) was not used for data validation because the concentration of the duplicated sample is too low for accurate evaluation (< 10x MDL).
	WG438769	Nitrogen, ammonia	M350.1 Auto Salicylate w/gas diffusion	RA	Relative Percent Difference (RPD) was not used for data validation because the concentration of the duplicated sample is too low for accurate evaluation (< 10x MDL).
	WG438796	Phosphorus, total	M365.1 - Auto Ascorbic Acid (digest)	RA	Relative Percent Difference (RPD) was not used for data validation because the concentration of the duplicated sample is too low for accurate evaluation (< 10x MDL).
	WG438313	Residue, Non-Filterable (TSS) @105C	SM2540D	RA	Relative Percent Difference (RPD) was not used for data validation because the concentration of the duplicated sample is too low for accurate evaluation (< 10x MDL).
	WG439029	Tin, total	M200.8 ICP-MS	M2	Matrix spike recovery was low, the recovery of the associated control sample (LCS or LFB) was acceptable.

Calico Monitoring Well Sampling

ACZ Project ID: L41754
Date Received: 12/13/2017 11:59
Received By:
Date Printed: 12/14/2017

Receipt Verification

	YES	NO	NA
1) Is a foreign soil permit included for applicable samples?			X
2) Is the Chain of Custody form or other directive shipping papers present?	X		
3) Does this project require special handling procedures such as CLP protocol?		X	
4) Are any samples NRC licensable material?			X
5) If samples are received past hold time, proceed with requested short hold time analyses?	X		
6) Is the Chain of Custody form complete and accurate?	X		
7) Were any changes made to the Chain of Custody form prior to ACZ receiving the samples?		X	

Samples/Containers

	YES	NO	NA
8) Are all containers intact and with no leaks?	X		
9) Are all labels on containers and are they intact and legible?	X		
10) Do the sample labels and Chain of Custody form match for Sample ID, Date, and Time?	X		
11) For preserved bottle types, was the pH checked and within limits? [1]	X		
12) Is there sufficient sample volume to perform all requested work?	X		
13) Is the custody seal intact on all containers?			X
14) Are samples that require zero headspace acceptable?			X
15) Are all sample containers appropriate for analytical requirements?	X		
16) Is there an Hg-1631 trip blank present?	X		
17) Is there a VOA trip blank present?			X
18) Were all samples received within hold time?	X		

NA indicates Not Applicable

Chain of Custody Related Remarks

Client Contact Remarks

Shipping Containers

Cooler Id	Temp(°C)	Temp Criteria(°C)	Rad(µR/Hr)	Custody Seal Intact?
NA27494	3.9	<=6.0	15	Yes

Was ice present in the shipment container(s)?

Yes - Wet ice was present in the shipment container(s).

Client must contact an ACZ Project Manager if analysis should not proceed for samples received outside of their thermal preservation acceptance criteria.

If sample(s) received past holding time (HT), or if insufficient HT remains to complete analysis before expiration, shall ACZ proceed with requested short HT analyses? YES [X] NO [ ]

If "NO" then ACZ will contact client for further instruction. If neither "YES" nor "NO" is indicated, ACZ will proceed with the requested analyses, even if HT is expired, and data will be qualified

Are samples for SDWA Compliance Monitoring? Yes [ ] No [✓]

If yes, please include state forms. Results will be reported to PQL for Colorado.

Sampler's Name: Kurt Newbry **Sampler's Site Information** **State** ID **Zip code** 83706 **Time Zone** MTN

Project ID:
ACZ Project ID: L45855

Jason Thompson:

Enclosed are the analytical results for sample(s) submitted to ACZ Laboratories, Inc. (ACZ) on July 26, 2018. This project has been assigned to ACZ's project number, L45855. Please reference this number in all future inquiries.

All analyses were performed according to ACZ's Quality Assurance Plan. The enclosed results relate only to the samples received under L45855. Each section of this report has been reviewed and approved by the appropriate Laboratory Supervisor, or a qualified substitute.

Except as noted, the test results for the methods and parameters listed on ACZ's current NELAC certificate letter (#ACZ) meet all requirements of NELAC.

This report shall be used or copied only in its entirety. ACZ is not responsible for the consequences arising from the use of a partial report.

All samples and sub-samples associated with this project will be disposed of after September 12, 2018. If the samples are determined to be hazardous, additional charges apply for disposal (typically $11/sample). If you would like the samples to be held longer than ACZ's stated policy or to be returned, please contact your Project Manager or Customer Service Representative for further details and associated costs. ACZ retains analytical raw data reports for ten years.

If you have any questions or other needs, please contact your Project Manager.

Sue Webber has reviewed and approved this report.

Project ID:
ACZ Project ID: L45855

Sample Receipt

ACZ Laboratories, Inc. (ACZ) received 2 groundwater samples from SPF Water Engineering on July 26, 2018. The samples were received in good condition. Upon receipt, the sample custodian removed the samples from the cooler, inspected the contents, and logged the samples into ACZ's computerized Laboratory Information Management System (LIMS). The samples were assigned ACZ LIMS project number L45855. The custodian verified the sample information entered into the computer against the chain of custody (COC) forms and sample bottle labels.

Holding Times

All analyses were performed within EPA recommended holding times.

Sample Analysis

These samples were analyzed for inorganic parameters. The individual methods are referenced on both, the ACZ invoice and the analytical reports. The following required further explanation not provided by the Extended Qualifier Report:

1. Tin, dissolved (B1) - Dissolved Tin was flagged with a "B1" in the QC Summary since tin was detected in the ICB over the limit at 0.00046 mg/L. No further action was taken since dissolved tin was not detected in the sample.

Report Header Explanations

Batch	A distinct set of samples analyzed at a specific time
Found	Value of the QC Type of interest
Limit	Upper limit for RPD, in %.
Lower	Lower Recovery Limit, in % (except for LCSS, mg/Kg)
MDL	Method Detection Limit. Same as Minimum Reporting Limit unless omitted or equal to the PQL (see comment #5). Allows for instrument and annual fluctuations.
PCN/SCN	A number assigned to reagents/standards to trace to the manufacturer's certificate of analysis
PQL	Practical Quantitation Limit. Synonymous with the EPA term "minimum level".
QC	True Value of the Control Sample or the amount added to the Spike
Rec	Recovered amount of the true value or spike added, in % (except for LCSS, mg/Kg)
RPD	Relative Percent Difference, calculation used for Duplicate QC Types
Upper	Upper Recovery Limit, in % (except for LCSS, mg/Kg)
Sample	Value of the Sample of interest

QC Sample Types

AS	Analytical Spike (Post Digestion)	*LCSWD*	Laboratory Control Sample - Water Duplicate
ASD	Analytical Spike (Post Digestion) Duplicate	*LFB*	Laboratory Fortified Blank
CCB	Continuing Calibration Blank	*LFM*	Laboratory Fortified Matrix
CCV	Continuing Calibration Verification standard	*LFMD*	Laboratory Fortified Matrix Duplicate
DUP	Sample Duplicate	*LRB*	Laboratory Reagent Blank
ICB	Initial Calibration Blank	*MS*	Matrix Spike
ICV	Initial Calibration Verification standard	*MSD*	Matrix Spike Duplicate
ICSAB	Inter-element Correction Standard - A plus B solutions	*PBS*	Prep Blank - Soil
LCSS	Laboratory Control Sample - Soil	*PBW*	Prep Blank - Water
LCSSD	Laboratory Control Sample - Soil Duplicate	*PQV*	Practical Quantitation Verification standard
LCSW	Laboratory Control Sample - Water	*SDL*	Serial Dilution

QC Sample Type Explanations

Blanks	Verifies that there is no or minimal contamination in the prep method or calibration procedure.
Control Samples	Verifies the accuracy of the method, including the prep procedure.
Duplicates	Verifies the precision of the instrument and/or method.
Spikes/Fortified Matrix	Determines sample matrix interferences, if any.
Standard	Verifies the validity of the calibration.

ACZ Qualifiers (Qual)

B	Analyte concentration detected at a value between MDL and PQL. The associated value is an estimated quantity.
H	Analysis exceeded method hold time. pH is a field test with an immediate hold time.
L	Target analyte response was below the laboratory defined negative threshold.
U	The material was analyzed for, but was not detected above the level of the associated value. The associated value is either the sample quantitation limit or the sample detection limit.

Method References

Comments

(1)	QC results calculated from raw data. Results may vary slightly if the rounded values are used in the calculations.
(2)	Soil, Sludge, and Plant matrices for Inorganic analyses are reported on a dry weight basis.
(3)	Animal matrices for Inorganic analyses are reported on an "as received" basis.
(4)	An asterisk in the "XQ" column indicates there is an extended qualifier and/or certification qualifier associated with the result.
(5)	If the MDL equals the PQL or the MDL column is omitted, the PQL is the reporting limit.

For a complete list of ACZ's Extended Qualifiers, please click: http://www.acz.com/public/extquallist.pdf

Date Printed: 7/27/2018

Receipt Verification

	YES	NO	NA
1) Is a foreign soil permit included for applicable samples?			X
2) Is the Chain of Custody form or other directive shipping papers present?	X		
3) Does this project require special handling procedures such as CLP protocol?		X	
4) Are any samples NRC licensable material?			X
5) If samples are received past hold time, proceed with requested short hold time analyses?	X		
6) Is the Chain of Custody form complete and accurate?	X		
7) Were any changes made to the Chain of Custody form prior to ACZ receiving the samples?	X		

A change was made in the Copy of Report to: E-Mail. Sample ID: Matrix section prior to ACZ custody.

Samples/Containers

	YES	NO	NA
8) Are all containers intact and with no leaks?	X		
9) Are all labels on containers and are they intact and legible?	X		
10) Do the sample labels and Chain of Custody form match for Sample ID, Date, and Time?	X		
11) For preserved bottle types, was the pH checked and within limits? [1]	X		
12) Is there sufficient sample volume to perform all requested work?	X		
13) Is the custody seal intact on all containers?			X
14) Are samples that require zero headspace acceptable?			X
15) Are all sample containers appropriate for analytical requirements?	X		
16) Is there an Hg-1631 trip blank present?	X		
17) Is there a VOA trip blank present?			X
18) Were all samples received within hold time?	X		

NA indicates Not Applicable

1 INTRODUCTION

This groundwater characterization report has been prepared to describe the groundwater conceptual model for the Calico Resources USA Corp's (Calico) Grassy Mountain Gold Project (Project). The groundwater conceptual model was defined as an objective of the groundwater resources baseline study in the *Environmental Baseline Study Work Plans, Grassy Mountain Project* (EM Strategies 2017) referred to as the Work Plan in this report.

The 2017 Work Plan Section 3.4.1 states the following as objectives of the groundwater baseline study:

- *Develop a conceptual model of the nature and interaction of the various water-bearing units and aquitards in relation to relevant geologic structures. The conceptual model should identify which water-bearing units are hydraulically*

connected (i.e., the same aquifer) and whether each aquifer is unconfined, semi-confined, or confined.

- *Accurately characterize the study area ground water resources, both quality and quantity, and the pre-project "environmental baseline." This includes springs in the vicinity of Grassy Mountain.*

The *Groundwater Resources Baseline Data Report, Grassy Mountain Gold Project* (SPF, 2021a summarizes the groundwater baseline data as required by the Work Plan for the proposed Grassy Mountain Gold Project, including:

- A description of sampling and monitoring events, including water quality, spring flow, and groundwater levels
- Sampling sites, including monitoring wells, baseline springs, and background springs
- Data collection methods
- Groundwater levels, both manual and continuous measurements
- Groundwater contour maps
- Spring and artesian well flow data
- Groundwater quality data from both wells and springs
- Comparison of groundwater quality data to drinking water standards (wells) and to drinking water standards and water quality standards (springs)
- Geochemical analysis of wells and springs
- Quality assurance and quality control results

This groundwater characterization report is intended to evaluate and analyze the groundwater baseline data and other relevant information to develop a groundwater conceptual model of the Project to meet the objectives of the Work Plan.

2 WATER RESOURCES STUDY AREA

The Project is located in Malheur County, Oregon, approximately 22 miles south-southwest of Vale (Figure 1) and consists of two areas: The Mine and Process Area and the Access Road Area (Permit Area) (Figure 2).

The Mine and Process Area is located on three patented lode mining claims and unpatented lode mining claims that cover an estimated 886 acres. These patented and unpatented lode mining claims are part of a larger land position that includes 455 unpatented lode mining claims and nine mill site claims on lands administered by the Bureau of Land Management (BLM) (Figure 2). All proposed mining would occur on the patented claims, with some mine facilities on unpatented claims. The Mine and Process Area is in all or portions of Sections 5 through 8, Township 22 South, Range 44 East (T22S, R44E) (Willamette Meridian).

The Access Road Area is located on public land administered by the BLM, and private land controlled by others (Figure 2). A portion of the Access Road Area is a Malheur County Road

named Twin Springs Road. The Access Road Area extends north from the Mine and Process Area to Russell Road, a paved Malheur County road. The Access Road Area is in portions of Section 5, T22S, R44E, Sections 3, 10, 11, 14, 15, 21 through 23, 28, 29, and 32, T21S, R44E, Sections 1, 12 through 14, 23, 26, 27, and 34, T20S, R44E, Sections 6 and 7, T20S, R45E, and Sections 22, 23, 26, 35, and 36, T19S, R44E (Willamette Meridian). The width of the Access Road Area is 300 feet (150 feet on either side of the access road centerline) to accommodate possible minor widening or rerouting, and a potential powerline adjacent to the access road. There are several areas shown that are significantly wider than 300 feet on the Permit Area Map (Figure 2), which are areas where the final alignment has not yet been determined. The final engineering of the road will be consistent throughout, and within the Permit Area. The Access Road Area also includes a buffer on either side of the proposed road width for the collection of environmental baseline data. The road corridor will be approximately 30 feet wide. The Access Road Area totals approximately 876 acres.

The Water Resources Study Area (Study Area) was established to develop an environmental water resources baseline for assessing potential impacts from Project facilities and to provide background data on nearby springs and on the Owyhee River and Lake. The Study Area includes an area encompassing the Mine and Process Area and two separate, non-contiguous, areas on the Owyhee River/Lake. A map of the Study Area is included as Figure 3. All of the baseline well and spring sites are located within the Study Area.

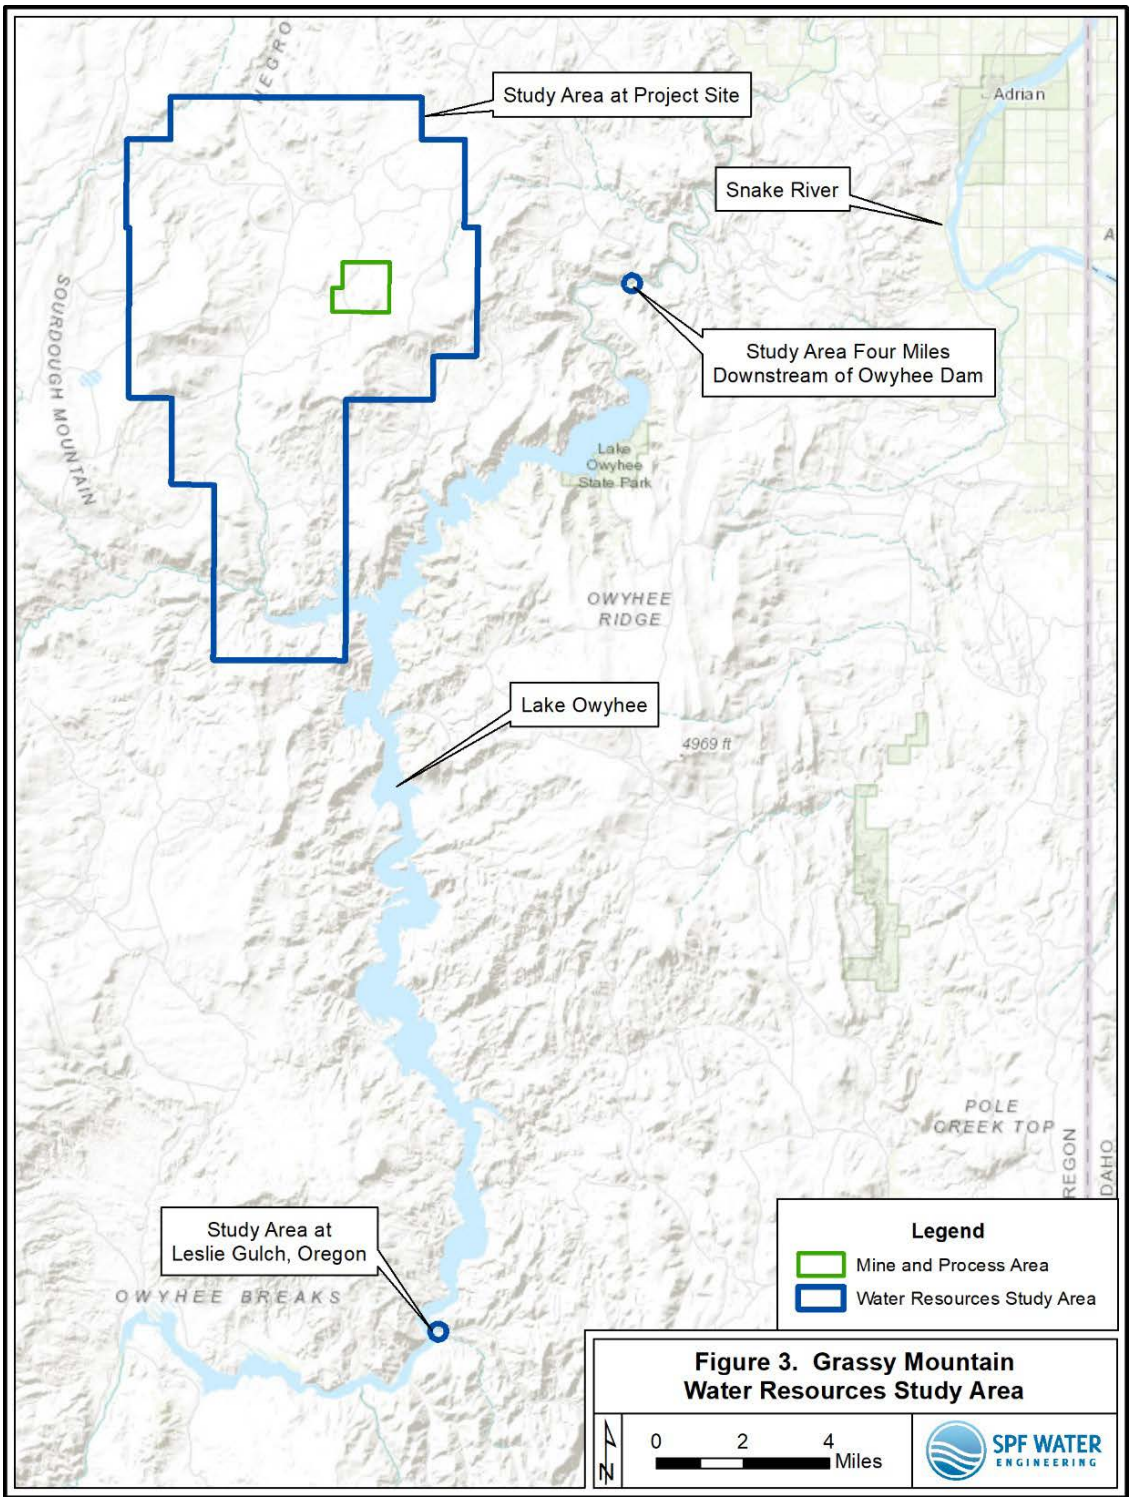

Figure 3. Grassy Mountain Water Resources Study Area

3 GEOLOGIC SETTING

3.1 Regional Geology

The following is excerpted from *Calico Resources USA Corp, Grassy Mountain Gold Project, Malheur County, Oregon, Geology and Soils Baseline Report* (Abrams, 2018):

Grassy Mountain is the largest of 12 recognized epithermal hot spring precious metal deposits of the Lake Owyhee volcanic field. The Lake Owyhee volcanic field occurs at the intersection of three tectonic provinces: the buried cratonic margin; the northern basin and range; and the Snake River Plain. During the mid-Miocene, large volume, peralkaline, caldera volcanism occurred in response to large, silicic magma chambers emplaced in the shallow crust throughout the region. The volcanic field includes several caldera-sourced ash-flow sheets and rhyolite tuff cones that were deposited from 15.5 to 15 million years ago (Ma).

At about 15 Ma, subsidence of the Lake Owyhee volcanic field triggered a change in volcanic eruption style, resulting in small volume, basalt-rhyolite deposits of limited extent. Volcanism during the mid to late Miocene is evidenced by small volume, metaluminous, high-silica rhyolite domes and flows, and small volume basalt flows and mafic vent complexes in north- and northwest-trending basin and range-type fracture zones and ring structures related to resurgent calderas. Regional extension and subsidence facilitated the formation of through-going fluvial systems and extensive lacustrine basins. Large volumes of fluvial sediments, sourced from the exhumed Idaho Batholith to the southeast were deposited in conjunction with volcanism and hot spring activity during the waning stages of volcanic field development. The resulting regional stratigraphic section is a thick sequence of mid-Miocene volcanic rocks and coeval-to-Pliocene age non-marine lacustrine, volcaniclastic, and fluvial sedimentary rocks.

A general description of the regional surficial geology is presented on a geologic map of Oregon (Ferns, et. al., 1993). Excerpts from this map are presented in Appendix A. Figure A1 shows that in the general vicinity of the Project, there is geologic unit *Tsau,* described as upper arkosic sandstone, conglomerate, and tuffaceous siltstone (upper and middle Miocene era). This unit is also referred to as the Grassy Mountain Formation. To the east of the Project, geologic unit *Tbcu* occurs, described as upper calc-alkaline lava flows (upper and middle Micocene). Holocene-age alluvium (*Qal*) occurs within the Twin Springs drainage to the west of the Project and to a lesser extent in the minor drainage extending north from the deposit. Figure A1 also shows the major faults near the Project.

Figure A2 includes the geologic map as a base with the surface water hydrologic unit borders, highlighted strikes and dips of the beds in unit *Tsau* (the Grassy Mountain Formation), and springs with their corresponding elevations. This map shows the contact between the Grassy Mountain Formation and the underlying Tuff of Kern Basin (unit *Ttkb*) where it surfaces at higher elevations to the west, south, southeast, and southwest on Grassy Mountain and Sourdough Mountain. The Grassy Mountain Formation generally strikes from east to west and dips towards the north with faulting, fractures, and folding that, in the vicinity of the Project site, create two graben or syncline features that extend down Negro Rock Canyon and

Sourdough Gulch. Between these two basin features is a horst block or anticline where the Tuff of Kern Basin surfaces approximately 0.9 miles west of the proposed Grassy Mountain Mine.

3.2 Study Area Geology

3.2.1 Geology in the Vicinity of Mine and Process Area

All of section 3.2 is excerpted from Abrams, 2018. Figure numbers have been updated from Abrams to fit sequentially within this report.

A representative stratigraphic column of the geologic units near the Mine and Process Area is included as Figure 4.

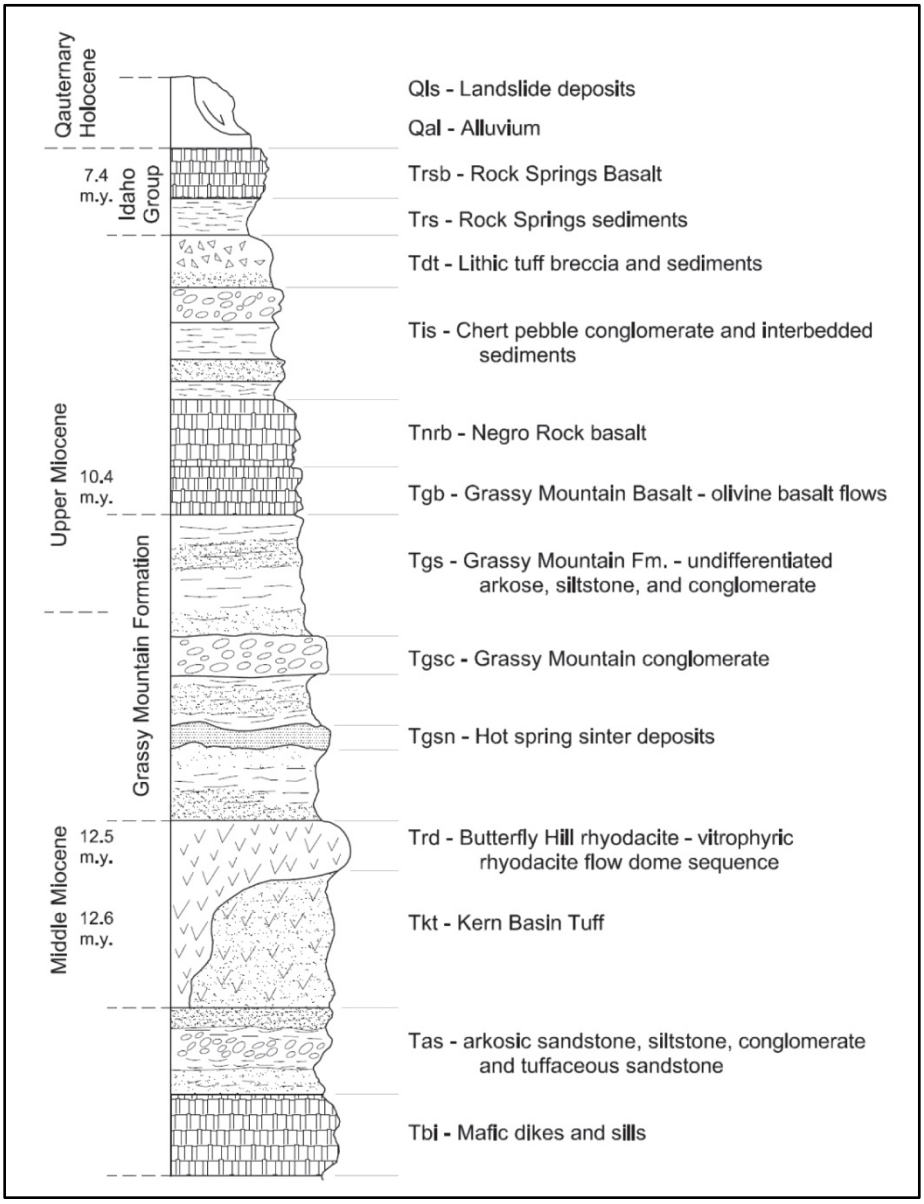

Figure 4. Representative stratigraphic column

Table 1 describes the stratigraphic column in more detail. The table describes the geologic units mapped near the Mine and Process Area, the unit's age and lithologic description, and provides the map symbols used to cross reference with the geologic units shown on Figure 5.

Table 1. Description of stratigraphic column

Map Symbol	Rock Unit	Age (millions of years before present in parentheses)	Description
Qal	Alluvium	Pleistocene and Holocene	Unconsolidated and generally poorly sorted deposits or gravel, sand and silt accumulated along modern streams, drainages and floodplains
Qls	Landslide deposits	Pleistocene and Holocene	Landslide and slump deposits of unconsolidated and unstratified soil and angular rock fragments formed as the result of bedrock failure. Includes large slump and debris flows composed of blocks of capping basalt on the flanks of Grassy Mountain and Sourdough Basin
Trsb	Rock Spring Basalt	Upper Miocene (7.4 Ma)	Snake River type olivine basalt flows and interbedded deposits of tuffaceous siltstone and sandstone. Unit is made up of approximately equal amounts of volcanic flows and interflow sedimentary rocks. Trsb flows range from two to 20 feet thick. Entire unit of basalt with sedimentary interbeds reaches maximum thickness of 400 feet east of Shell Rock Butte
Trs	Rock Spring Basalt – tuffaceous siltstone and sandstone	Upper Miocene	Sandstone and tuffaceous siltstone interbedded with unit Trsb are mapped separately where well exposed. Upper beds are mainly tuffaceous siltstones and include some bentonitic clays
Tdt	Lithic tuff breccias	Upper Miocene	Mafic clast lithic tuff, airfall tuffs and overlying reworked tuffaceous silt and sandstones. Breccia clasts include yellow inflated pumice and basaltic scoria. Distinguished from Tkt by absence of banded rhyolite clasts and absence of biotite and hornblende phenocrysts that are present in Tkt. Unit is approximately 80 feet thick in western portion of map.

Map Symbol	Rock Unit	Age (millions of years before present in parentheses)	Description
			Unconformably overlies Tis and is conformably overlain by Trsb
Tnrb	Negro Rock Basalt	Upper Miocene	Dark brownish gray, locally flow banded basalt. Dikes, plugs and sills are common. Typically, higher Fe/Mg ratios and much lower chromium content than Tgb or Trsb
Tgb	Grassy Mountain Basalt	Upper Miocene (10.4 Ma)	Flow on flow sequence of olivine basalts capping the summit of Grassy Mountain; includes somewhat younger intra-canyon flows forming benches on the south side of Grassy Mountain. Locally includes overlying stream gravels containing chert pebbles and large rounded basalt clasts. Maximum thickness of 200 feet; individual flows up to 40 feet thick
Tis	Interbedded conglomerate and siltstone	Upper Miocene	Chert pebble conglomerate and interbedded diatomaceous siltstone. Mainly tuffaceous and arkosic sandstone and siltstone with interbedded conglomerate. Locally becomes finer grained upward into pale, white and yellow claystones and interbedded diatomaceous siltstones. Presumed base of Tis near Grassy Mountain Reservoir contains black chert-pebble and granite-clast conglomerate. Erosional contact with underlying unit Tgs marked by rounded boulders of olivine basalt unit Tgb. Unit is approximately 400 feet thick in mapped area
Tgs	Grassy Mountain Formation – undifferentiated	Upper and Middle Miocene	Arkosic sandstones and channel-fill granite clast conglomerates. Mainly white to tan arkosic sandstones. Includes Tgsc, channel fill conglomerates with abundant granite and rhyolite clasts in the upper part of the unit. Uppermost conglomerates locally contain rounded obsidian clasts and rare black chert clasts. Unit Tgs generally

Map Symbol	Rock Unit	Age (millions of years before present in parentheses)	Description
			becomes finer grained upward and includes white bentonitic clays near the top of the section which, where overlain by unit Tgb often generated large landslide masses. Hot spring activity contemporaneous with the deposition of the arkoses is indicated by sinter beds Tgsn, and sinter boulders containing silicified reeds and wood near the Grassy mountain gold deposit. Unit Tgs is the host for both the Grassy Mountain and Crabgrass gold deposits
Tgsc	Grassy Mountain Formation – Conglomerate		Conglomerates occurring in the upper portion of Tgs – mapped individually where possible
Tgsn	Grassy Mountain Formation – Sinter		Hot spring sinter deposits within Tgs – mapped individually where possible
Trd	Butterfly Hill Rhyodacite	Middle Miocene (12.5 Ma)	Ryodacite flow dome complex
Tkt	Kern Basin Tuff	Middle Miocene	Mainly non-welded fine-grained, white to pale-yellow lithic tuff contain basalt, banded rhyolite, and white pumice clasts with biotite, hornblende, quartz and plagioclase crystals. Includes thinly bedded airfall tuffs at the base of the unit and overlying thin lenses of interbedded tuffaceous and arkosic sandstone and granite-clast conglomerate. Locally includes chaotically bedded airfall tuff with slump structures and massive surge deposits of matrix-supported lithic tuff composed of rhyolite and pumice clasts. Pumice clasts in the lithic tuff deposits increase in abundance and size toward the top of the unit. Uncomformably overlies unit Tas

Map Symbol	Rock Unit	Age (millions of years before present in parentheses)	Description
Tas	Arkosic and tuffaceous sandstone	Middle Miocene	Arkosic and tuffaceous sandstone, siltstone and conglomerate. Mainly white to tan arkosic sandstone with minor amounts of granite-clast conglomerate. Includes 20 feet thick massive beds of coarse matrix supported, granite-clast conglomerate near the exposed base of the unit
Tbi	Mafic dikes and sills	Middle Miocene	Mafic dikes and sills. Younger sequence includes irregularly shaped sills and dikes that intrude units Tas, Tkt and Tgs along both flanks of Grassy Mountain. Dikes and sills are olivine basalts believed to be feeders to units Tbg and Trsb. Dike cut through lowermost flows of unit Trsb north of Grassy Mountain near Willow Spring

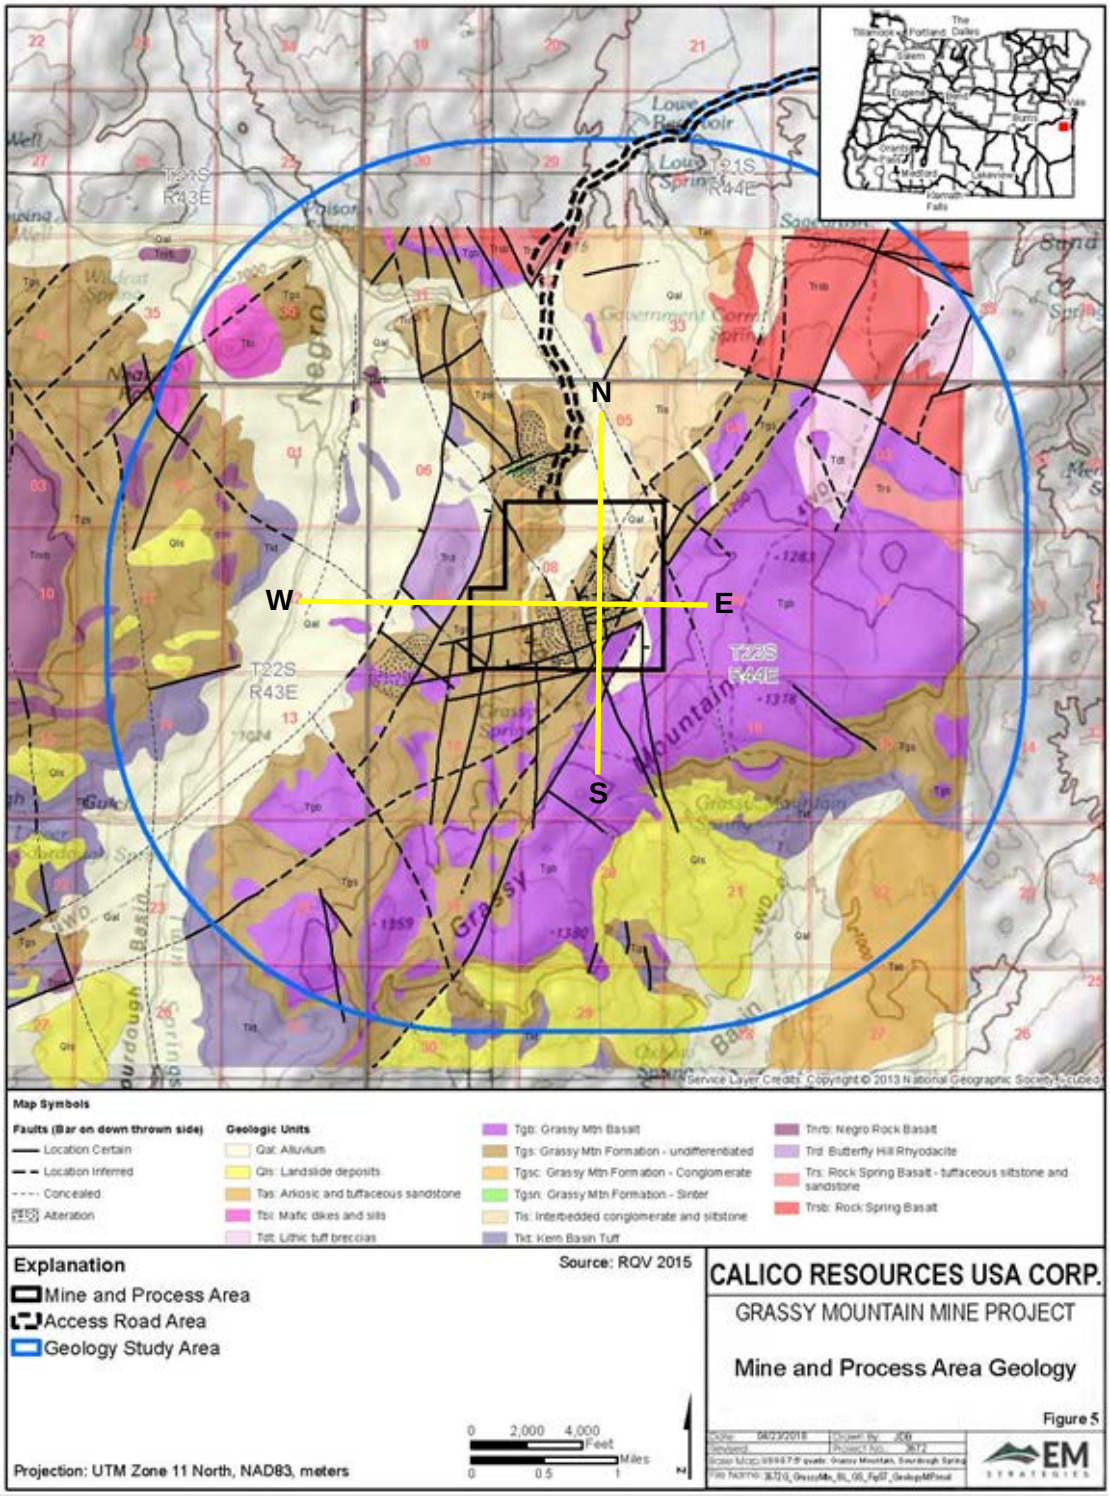

Figure 5. Mine and Process Area Geology

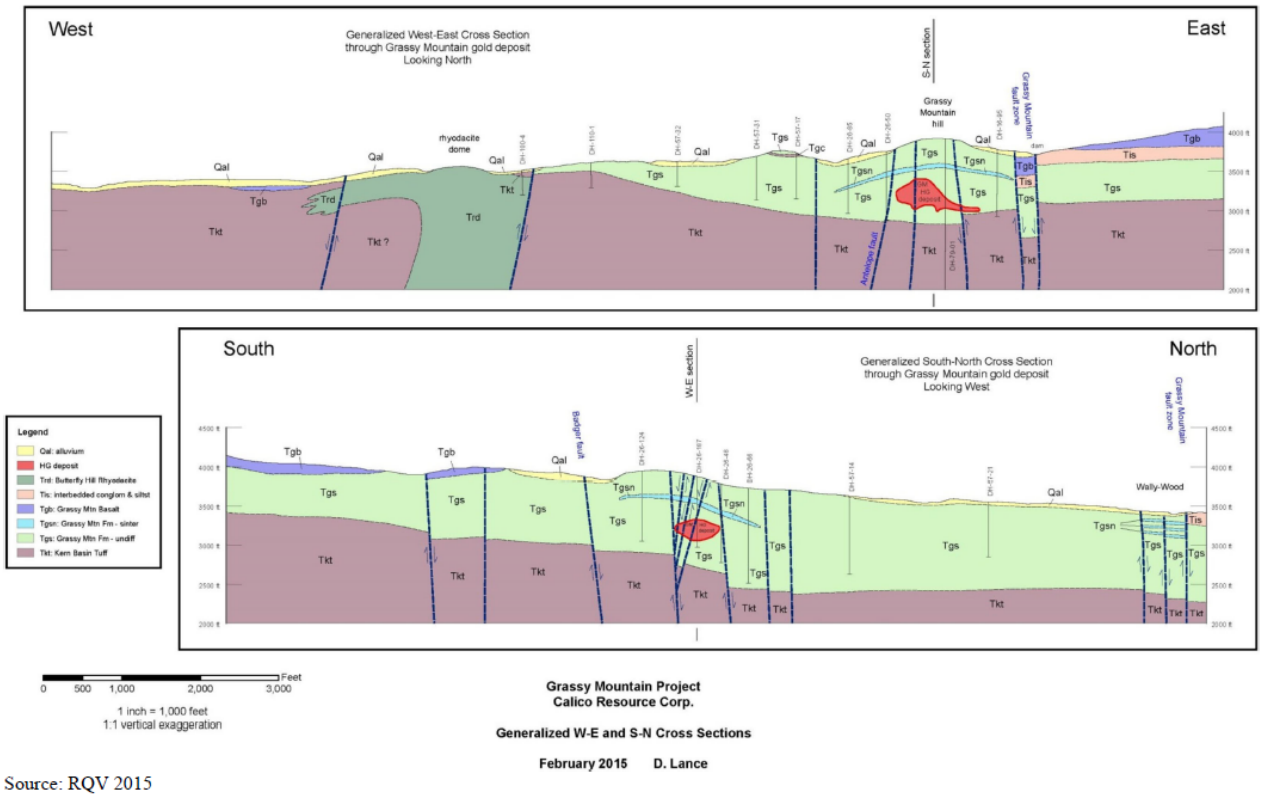
Bedrock outcrops near the Mine and Process Area are typically composed of olivine-rich basalt and siltstones, sandstones, and conglomerates of the late Miocene Grassy Mountain Formation (Tgb, Tgsn, and Tgs). These rocks are locally covered with relatively thin, unconsolidated alluvial and colluvial deposits (Qal). Erosion-resistant basalts cap local topographic highs. Arkosic sandstones have been encountered at the surface and at depth but have not been correlated across the vicinity of the Mine and Process Area, in part due to lateral discontinuity associated with sedimentary facies changes and structural offset.

Figure 6 *shows two generalized geologic cross sections through the Mine and Process area; west to east and south to north* (the original Figure 7 in Abrams did not include the cross-section lines; these have been added to Figure 5 above as depicted on Figure 5-2 in Red Quill Ventures 2015).



Source: RQV 2015

Figure 6. Geologic Cross Sections

The basal unit below the Grassy Mountain Formation is the Kern Basin Tuff (Tkt); a nonwelded, pumiceous, crystal tuff that displays cross beds and local surge structures. Clast size, thickness of individual ash units, and bedding structures suggest a source in the Grassy Mountain area. The Kern Basin Tuff ranges in thickness from 300 feet on the south bluffs of Grassy Mountain, to 1,500 feet in a drill hole beneath the Mine and Process Area.

The Kern Basin Tuff is overlain by a series of fluvial sediments. Most of the sedimentary units in and near the Mine and Process Area are silicified and strongly indurated. These sedimentary units include granitic clast conglomerate, arkosic sandstone, fine grained sandstone, siltstone, and siltstone/mudstone. The sedimentary facies of the Grassy Mountain Formation range from 300 to over 1,000 feet thick and provide the host rocks of the Grassy Mountain mineral resource.

Several siliceous terraces are interbedded with the silicified sediments of the Grassy Mountain Formation. Terrace construction was apparently episodic and intermittently inundated by fluvial sediments, resulting in an interbedded sequence of siltstone, sandstone, conglomerate, and sinter terrace deposits. Load casts, flame textures, convolute lamination and other soft-sediment deformation textures are common in both the sinter beds and sedimentary facies. The amount and size of the sinter clasts in the sedimentary rocks reflect relative proximity to a terrace. Proximal deposits are angular, inhomogeneous, clast-supported breccias of sandstone, siltstone, and sinter with indistinct clast boundaries in a sulfidic mud-textured matrix.

3.2.2 Ore Deposit Geology, Mineralization, and Alteration

The Grassy Mountain gold-silver deposit is located beneath a prominent, 150-foot high, silicified and iron-stained hill. Bedding is horizontal at the hilltop, and dips at ten to 25 degrees to the north-northeast on the northern and eastern flanks of the hill. The bedding dip steepens to 30 to 40 degrees on the west side of the hill due to drag folding in the footwall of the 20 degrees west of north (N20°W), striking Antelope Fault. A small area on the southwest slope of the deposit hill is covered by silicified arkose landslide debris.

The Grassy Mountain gold-silver deposit is located within an interpreted horst block that has been raised 50 to 200 feet in a region of complex block faulting and rotation. Faults at the Grassy Mountain deposit are mainly post-mineral 30 degrees west of north (N30°W) to ten degrees east of north (N10°E), striking normal faults developed during basin and range extension. On the northeast side of the deposit, these faults progressively downdrop mineralization beneath post-mineral cover. These offsets are suggested by interpreted offsets of a prominent white sinter bed in drill holes, as well as drill intersections with fault gouge.

The surface expression of the Grassy Mountain gold-silver system is indicated by weak to moderately strong silicification and iron staining with scattered one-eighth inch to one inch wide creamy to light gray chalcedonic veinlets. Approximate dimensions of the Grassy Mountain deposit at depth are 1,600 feet long by 1,000 feet wide by 600 feet thick. The deposit has a general 70 degrees east of north (N70°E) elongation and an approximate 15-degree bedding plane dip in a northerly direction due to faulting and associated fault block rotation.

There is an envelope of lower grade mineralization at depths of 200 to 800 feet that contains a higher-grade zone of mineralization between 500 and 750 feet below the surface. The well-defined base of higher grade mineralization from approximately 700 to 750 feet in depth suggests a strong pressure-temperature control on gold deposition. This pressure-temperature control likely indicates a boiling horizon in the hydrothermal system that acted as a controlling mechanism on gold deposition.

Silicification in the form of sinters and disseminated quartz is a prominent alteration type at Grassy Mountain and is largely controlled by hot-spring vents. Silicification occurs both pervasively as silica flooding, and as cross-cutting veins and stockworks. The silicified envelope has plan dimensions up to 3,000 feet (north-south) by 2,500 feet (east-west). Silicification is surrounded by widespread, barren, clay-rich (20- to 40-percent montmorillonite), tuffaceous siltstone and arkose with minor disseminated pyrite. Many of the sinters occur as sheets instead of mounds, which suggest that they are related to vents along faults rather than point sources.

Mineralization of the Grassy Mountain deposit includes: low grade gold associated with hot springs silicification; high grade gold associated with multi-stage quartz-adularia-gold-silver veins and stockworks; and late remobilization within sub-vertical rubble zones defined by clay matrix breccias. The deposit is characterized by stacked sinter terraces capping acid-leached sediments and multiple generations of quartz veins, which suggest repeated eruption, brecciation, breeching, and sealing of the hydrothermal system.

3.2.3 Structural Geology

At a local scale and within the immediate vicinity of the Grassy Mountain gold deposit, fault orientations can be grouped into two major sets: 20 degrees west of north to ten degrees east of north (N20°W to N10°E) striking faults, and 70 degrees east of north (N70°E) striking faults. These structures will have the greatest impact on underground conditions within the mining environment.

As depicted on the cross sections (Figure 6), faulted offsets are generally less than 40 to 50 feet. Maximum offsets of up to 200 feet occur along the N20°W striking Grassy Mountain fault zone.

4 HYDROGEOLOGIC FRAMEWORK

4.1 Introduction

The discussion below summarizes the hydrogeologic framework for vicinity aquifer conditions, groundwater elevation (potentiometric surface), hydraulic gradients (horizontal and vertical), and the potential influence of faults and structural controls on groundwater occurrence and flow.

The current understanding of groundwater trends is based on the following sources of information, compiled during investigations conducted between the late 1980s and the present:

- Drillers' reports and accounts of water encountered during borehole drilling and production during well test pumping activities
- Direct measurement of groundwater levels over time in production and monitoring wells installed in the vicinity surrounding the proposed Grassy Mountain Mine
- Vibrating wire piezometers (VWPs) installed directly within the deposit (deposit area) as point measurement locations.
- Controlled-source audio-frequency magnetotelluric (CSAMT) data used to characterize differences in porosity, often controlled by silicification.

4.2 Baseline Groundwater Level and Flow Monitoring

4.2.1 Monitoring Well Network

The monitoring well network has been developed over the course of 30 years for the purpose of collecting groundwater baseline data for the Project. While mining plans have changed over time, the original wells and subsequent additions have created a flexible and comprehensive baseline monitoring platform. The network currently includes 32 wells and piezometers, ranging in depth from 25 feet to 950 feet. There are wells and piezometers located in the near vicinity of the proposed mine and extending downgradient by several miles. The monitoring well network is described in the approved Work Plan and summarized below.

The first wells were constructed in support of baseline environmental studies conducted by Atlas Precious Metals, Inc. (Atlas). Western Technologies, Inc. oversaw the installation of three monitoring wells (GW-1, GW-2, and GW-3) and one production well (Prod-1) on the site in 1988.

The piezometers (26-092-915, 57-1, 57-10, 89-2) were installed in exploratory drill holes by Atlas, presumably shortly after drilling the holes in 1988 and 1989.

In 1989 and 1990, Steffen Robertson and Kirsten Consulting, Inc. oversaw the installation of monitoring well GW-4 and the production wells (PW-1 and PW-4). In 1991, J.M. Montgomery Consulting Engineers, Inc. (JMM) oversaw construction of three monitoring wells (GW-3A, GW-5, and GW-6) and one piezometer (GW-3B).

In 1993, twelve (12) new test and monitoring wells were installed, with work documented by Hydro-Geo Consultants, Inc. These were 59760, 59761, 59762, 59763, 59764, 59765, 59766, 59767, 59768, 59769, 59770, 59772.

The most recent monitoring wells (GMW17-31, GMW17-32, GMW17-33, and GMW18-34 were constructed in 2017 and 2018 to provide groundwater monitoring locations upgradient and downgradient of the deposit area. The locations of these new wells were selected based on their proximity to the mine in both up and down gradient areas. Wells GMW17-32 and GMW17-33 are deep/shallow well pairs constructed in close proximity to evaluate vertical

gradients, hydraulic connectivity, aquifer static water levels, and groundwater quality. Well GMW17-33 was constructed as a shallow pairing with the pre-existing well 59762. Well GMW18-34 is a deep upgradient well where water was not detected during drilling, so a shallow companion well was not completed. The work plan for the Grassy Mountain monitoring wells was approved by DOGAMI by letter dated January 6, 2017. A work plan adjustment eliminating the shallow well pair for GMW18-34 was approved by DOGAMI by letter dated May 31, 2018.

Two wells are included in the monitoring well network that were not constructed as monitoring wells. These are the Bishop stockwater well (drilled in 1963) and the BLM stockwater well (drilled in 1972).

A list of wells, locations, construction details, measurement protocols, water level data, and hydrographs are presented in the groundwater baseline report (SPF, 2019). Well construction details are summarized in Table 2. The location of all the monitoring wells is shown on Figure 7

4.2.2 Shallow Monitoring Well Water Levels

Quarterly groundwater level measurements have been collected manually from eighteen (18) monitoring wells between the 1st Quarter of 2013 and the 3rd Quarter of 2018, with the exception of the 1st and 2nd Quarters of 2015[1]. During the 2nd and 3rd Quarters of 2014, another five (5) monitoring wells were added to the program[2]. Once completed, the new monitoring wells GMW17-31, GMW17-32, GMW17-33, and GMW18-34 were included in the quarterly water level monitoring, in accordance with the Final Work Plan for Grassy Mountain Monitoring Wells (SPF, 2016b). More details on the new monitoring wells are provided in the well completion reports for GMW17-31, GMW17-32, GMW17-33, and GMW18-34 (SPF, 2018a, SPF, 2108b). Continuous water level data have been obtained from three wells using water level pressure transducers since the 1st Quarter of 2013.

Approximately half of the shallow monitoring wells (depth of less than 500 feet) show relatively stable water levels (i.e., typically within +/- one foot) during the monitoring period between 2013 and 2018 (Figure B1 in Appendix B). Of these wells, GW-5, GW-4, PW-4, 57-10, GW-2, and BLM remained stable with relatively flat or slightly upward trending water levels from 2013 through 2018 and minor fluctuations attributed to seasonal recharge. Wells 59770, 59763, 59764, GW-6, and 89-2 had a slight downward trend with minor recharge fluctuations.

Wells without stable trends exhibited fluctuations that appear to be responses to recharge from high-precipitation years, from pumping, or from drilling activities. All of the non-stable trend hydrographs are explained in more detail in the baseline characterization report (SPF, 2019). The non-stable trends that provide insight into aquifer characteristics are discussed below.

[1] Due to a change in ownership of the project, no monitoring occurred during these two quarters.
[2] These wells were identifed after a more thorough review of the historical record.

Table 2. Well Construction Table

1 - as reported on the drillers log
2 - based on short-term testing by driller during or following construction
3 - based on long-term test pumping
4 - surveyed with the exception of GW-3A, GW-3, GMW-17-31, GMW17-32, GMW17-33, and GMW18-34

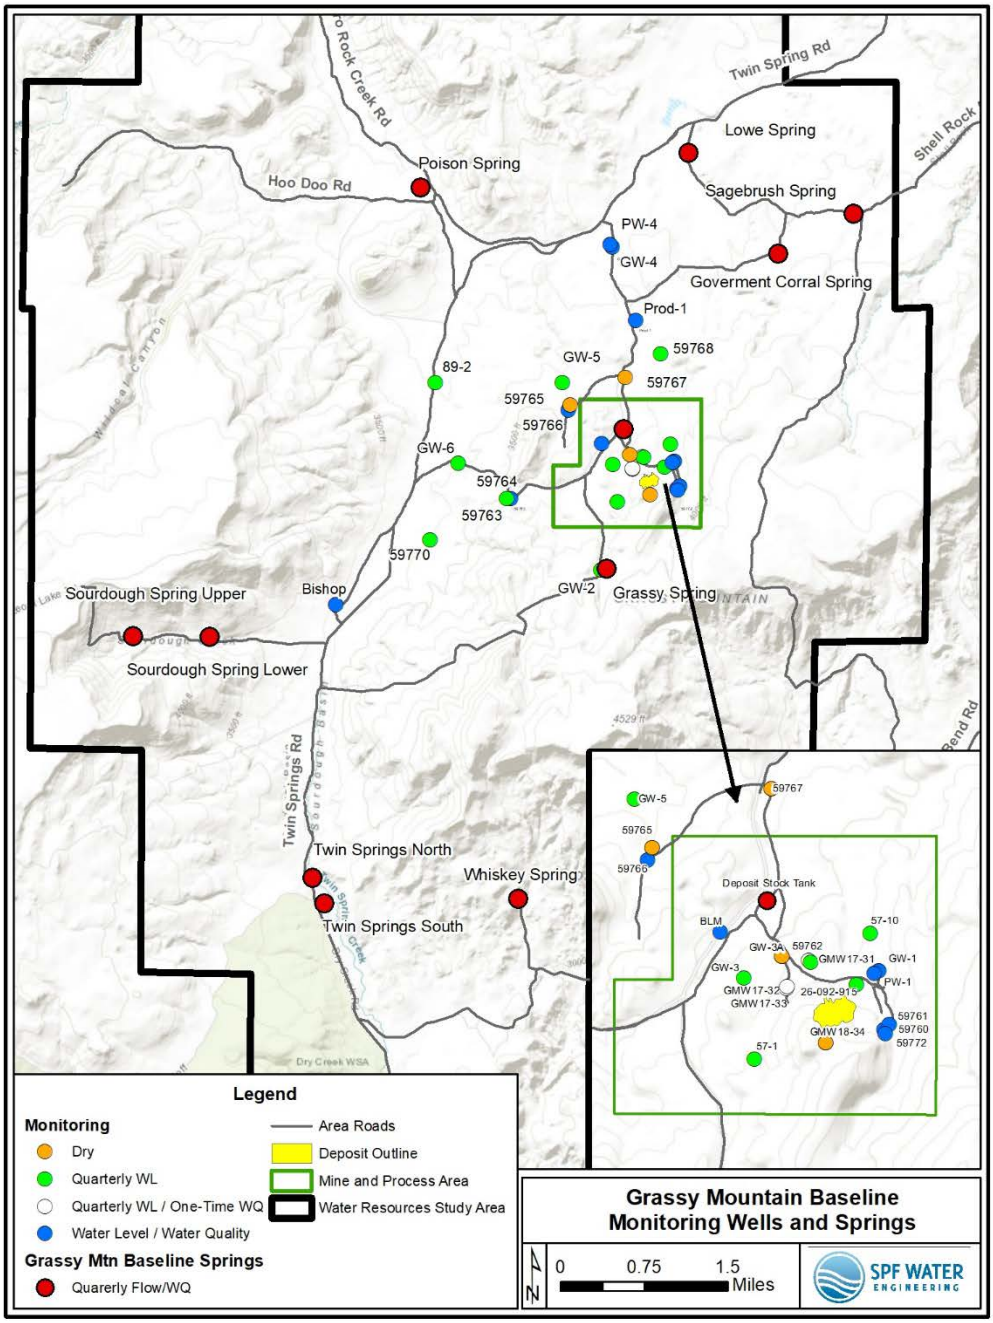

Figure 7. Grassy Mountain baseline monitoring wells and springs

4.2.2.1 GW-3 and GMW17-33

Monitoring well GW-3 water levels show possible influence from the drilling and pumping of the new monitoring wells. GW-3 is the closest monitoring well to the new monitoring wells drilled in 2017 and 2018, and has a relatively deeper completion interval than the rest of the historical monitoring wells drilled near the deposit area (screened interval from a depth of 320 to 350 feet [3314-3284 ft msl]). Monitoring well GW-3 had a stable to very slowly rising water level from the start of monitoring in 2013 until the 3rd Quarter of 2017 (Figure 8). Between the hand measurements on 09/26/2017 and 11/29/2017, the water level began declining, with approximately 5 feet of decline in one year. The start of this 5-foot decline coincided with the drilling of GMW17-33 (screened from 238 feet to 338 feet [3465-3365 ft msl]), during which the driller noted first hitting water on 11/17/2017, but before test pumping of any of the new wells.

On 11/29/2017 a transducer was installed in GW-3 for monitoring the water level during pumping tests of wells 59762, GMW17-32, and GMW17-33. Between 11/29/2017 and 12/28/2017 (transducer removal) the transducer recorded a drawdown of only 0.39 feet, with no drawdown or recovery trends apparent from any of the aquifer tests. With no significant drawdown in GW-3 apparent from the testing of GMW17-33 (average flow rate of 25.8 gpm for 97 hours between 12/14/2017 and 12/18/2017) prior to the transducer being pulled on 12/28/2017, it is theorized that the initial drop in water level first detected on 11/29/2017 may have been caused by delayed effects from the drilling of GMW17-32. This well was first drilled to approximately 1,000 feet by early September 2017. Water was first encountered on 8/25/2018 at a depth of 235 feet. Due to problems with hole instability, the well was re-drilled to 900 feet and the well was constructed by the end of October 2017.

Up through the most recent quarterly monitoring (3rd quarter 2018), both GW-3 and GMW17-33 show an average decline of approximately 1.25 feet per quarter and 2.5 feet per quarter, respectively, with both wells drawing down approximately 2.5 feet in the last quarter alone (Figure 9). The delayed drawdown in GW-3 may be a response to the drilling of GMW17-32, whereby the shallow aquifer zone drained into a deeper zone. GMW17-32 was ultimately constructed with 8-inch casing sealed to 656 feet (3046 ft msl), so the shallow aquifer zone can no longer drain into the deeper zone. The drawdown seen in GW-3 may also be a delayed response to test pumping of GMW17-33. The drawdown response indicates an aquifer with very low values of hydraulic conductivity and possible compartmentalization from the faults functioning as lesser permeable boundaries.

The observed drawdown in GMW17-33 through the 3rd Quarter of 2018 is likely not a response to test pumping. No shallow wells have been test pumped during the period of record. The deep wells that were test pumped have much deeper completions and were test pumped at very low pumping rates. It is possible that the initial static water level in the well was artificially high due to water used for drilling the well, although only a minor amount was needed. The well could still be equilibrating towards a "true" static water level. Another possibility is that there is a general decline in the shallow aquifer zone in the vicinity of the proposed Grassy Mountain Mine. Water level declines are noted in piezometer 26-092-915 and wells 59760,

59761, and 59772 located near the deposit area. Inadequately sealed boreholes at or near the deposit area may be the cause of shallow aquifer zones draining to deeper zones.

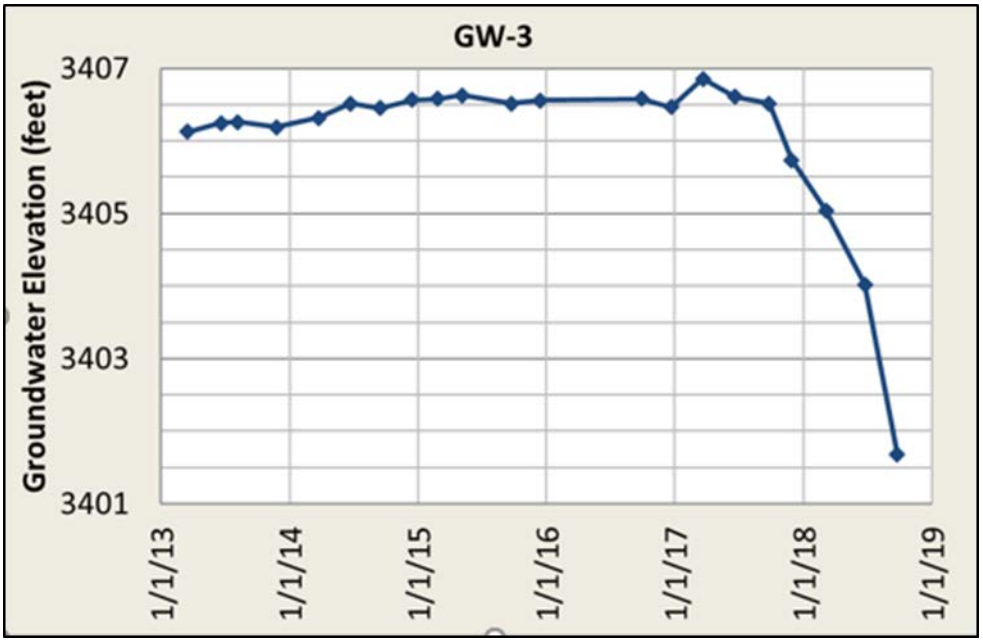

Figure 8. Groundwater hydrograph for monitoring well GW-3

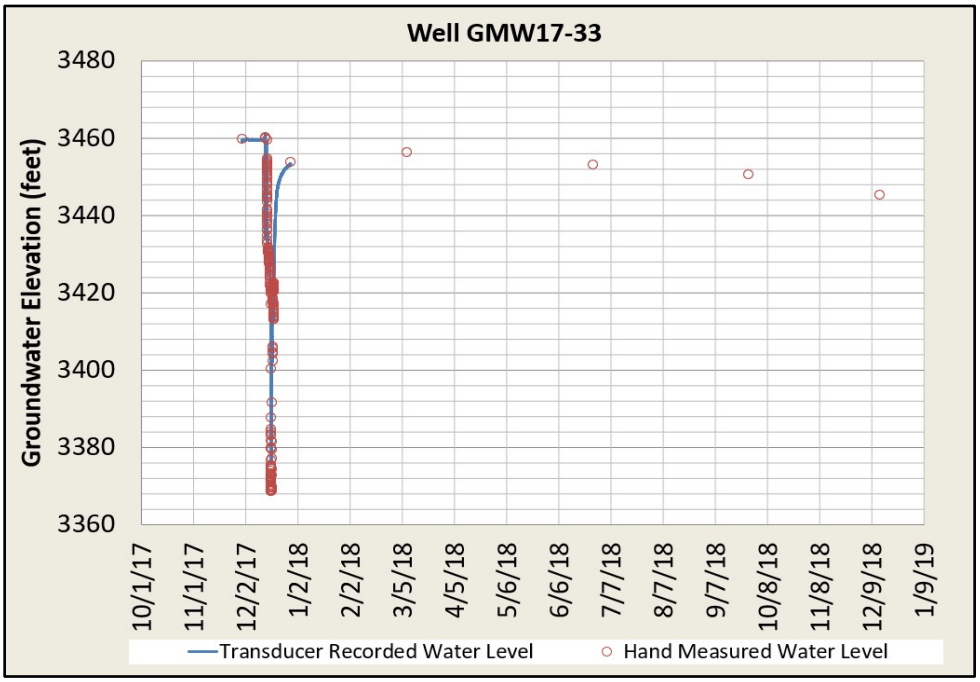

Figure 9. Groundwater hydrograph for well GMW17-33

4.2.2.2 GW-1, PW-1, and 26-092-915

Wells GW-1 and PW-1 seem to have a flat or slightly rising water level trend, which only varied during the 2016-17 pumping of PW-1 to support resource and reserve drilling activities (i.e., well construction water supply). PW-1 was used for drill water at various times between September 29, 2016, and March 22, 2017. The pumping rate and duration are not known, but the well is believed to be equipped with a pump capable of producing 20 to 30 gpm. The December 2016 monitoring event found that groundwater levels in wells GW-1 and PW-1 had declined by approximately 4 feet and 7 feet, respectively, from previous measurements. Water levels eventually rebounded to previous trends (Figure 10). The decline and rebound effects are attributed to intermittent pumping in PW-1.

The clear hydraulic response in well GW-1, screened in gravel deposits from approximately 135 feet to 155 feet bgs, suggest a hydraulic connection exists based on pumping in nearby well PW-1. PW-1 was reportedly screened within a deeper portion of the aquifer, from 320 feet to 340 feet (3389-3369 ft msl) in unconsolidated clay and sand deposits and from 400 feet to 420 (3309-3289 ft msl) feet in sandstone. The water well report for PW-1 indicates a seal from 320 feet to surface. Wells GW-1 and PW-1 are approximately 100 feet apart. It seems unlikely that the shallow aquifer tapped by GW-1 would be affected to the observed extent by pumping PW-1 given the layers of gravel and clay (13 feet), clay and sand (17 feet), basalt (125 feet), and brown clay (8 feet) existing between the two aquifer zones.

It is possible that PW-1 or other wells in the area are not adequately sealed allowing groundwater to flow from the upper to the lower aquifer zones. Another possibility is that faulting in this area functions as a conduit for groundwater flow. Like most of the monitoring wells in the area, the wells are located next to multiple faults, but unlike most of the monitoring wells, these wells are located (as indicated by the CSAMT survey) in an area that is less affected by silicification. Even with this possibility, the recovery period is still more four times longer than the pumping period (Figure 11) indicating lower transmissivity or negative hydraulic boundaries at some distance from the well.

26-092-915 is located approximately 500 feet from PW-1 and is screened at a depth of 228 to 268 feet (3482-3442 ft msl) (Figure 7). There was no observed drawdown in 26-092-915 during the period of intermittent pumping between 2016 and 2017 (Figure 12). Water levels steadily decline (~2.5 feet) from 2013 to the beginning of 2017 most likely associated with dry conditions. Water levels then increase 3 feet between 2017 and mid-2018 after increased precipitation in 2017. To evaluate the expected drawdown at 26-092-915 from pumping at PW-1 the Theis method was used assuming a pumping rate between 20 and 30 GPM at PW-1, a transmissivity of 250 gpd/ft, and a storativity of 10^{-5}. Under conditions where the wells were connected to the same water producing unit, the predicted drawdown at 26-092-915 would be approximately 40 feet after one day of continuous pumping. The aquifer properties used are based on results from historical pumping test discussed further in section 4.8.1. A

possible explanation lack of drawdown at 26-092-975 is the faults that run between PW-1 and 26-092-915 acting as a barrier to flow. The effect of faults on groundwater flow is discussed further in section 4.7.

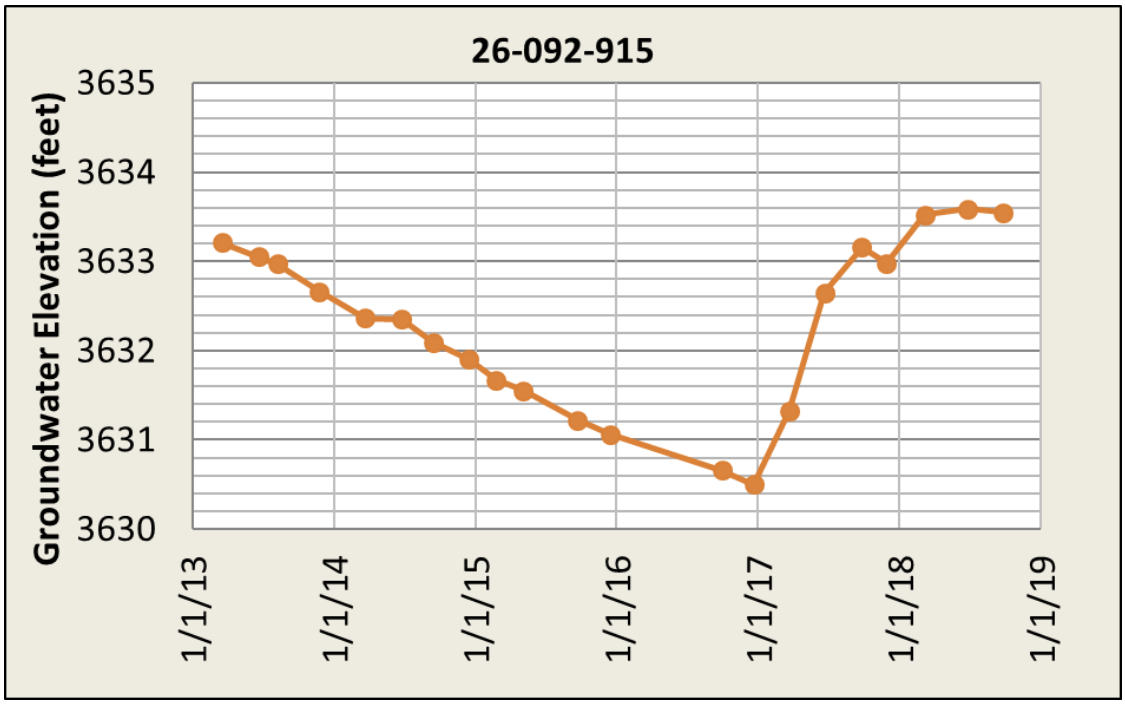

Figure 12. Groundwater Hydrograph for well 26-092-915

4.2.3 Deep Monitoring Well Water Levels

4.2.3.1 59762 and GMW17-32

Water levels have been monitored in Well 59762 since 2013. This well is screened from a depth of 537.5 feet to 657.5 feet (3175-3065 ft msl). Groundwater levels in monitoring well 59762 have shown a gradual decline of approximately 2 feet over five years, refer to Figure 13. The water level was 619.65 feet below measurement point (bmp) (3105 ft msl) on 3/18/2013 and was measured at 621.39 feet bmp (3103.4 ft msl) on 9/26/18. The driller's log reported a static water level of 626 feet on October 29, 1993.

It is possible that the observed decline is a result of slow leakage from the well screened interval downward due to vertical gradient. Another possible explanation is evaporation from the well exceeding infiltration.

The hydrograph showing water levels measured in GMW17-32 shows the results of test pumping and recovery; see Figure 14. The well was test pumped on December 11, 2017, with a starting static water level of 648.33 feet bmp (3054 ft msl) and an ending pumping water level of 717.70 feet bmp (2984 ft msl). The test is described in more detail in Section 4.8.2.2. Figure 14 shows that the water level in GMW17-32 appears to have completely recovered to a depth of approximately 620 feet bmp (3082 ft msl) by 6/26/2018; the water level measured on 9/26/2018 was very similar. Therefore, the water level in this well appears to have taken up to 200 days to completely recover from the test pumping, suggesting very low aquifer hydraulic conductivity.

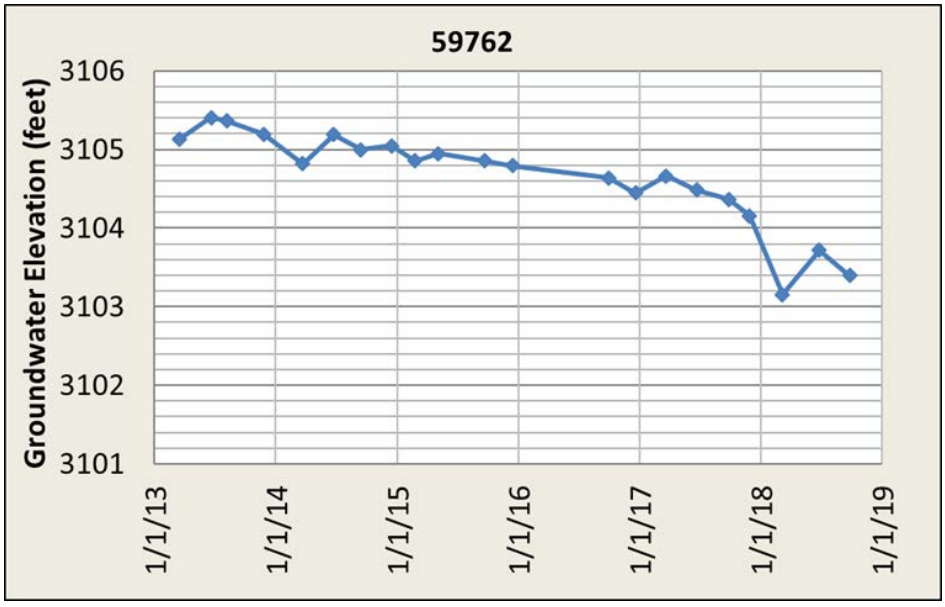

Figure 13. Groundwater hydrograph for 59762

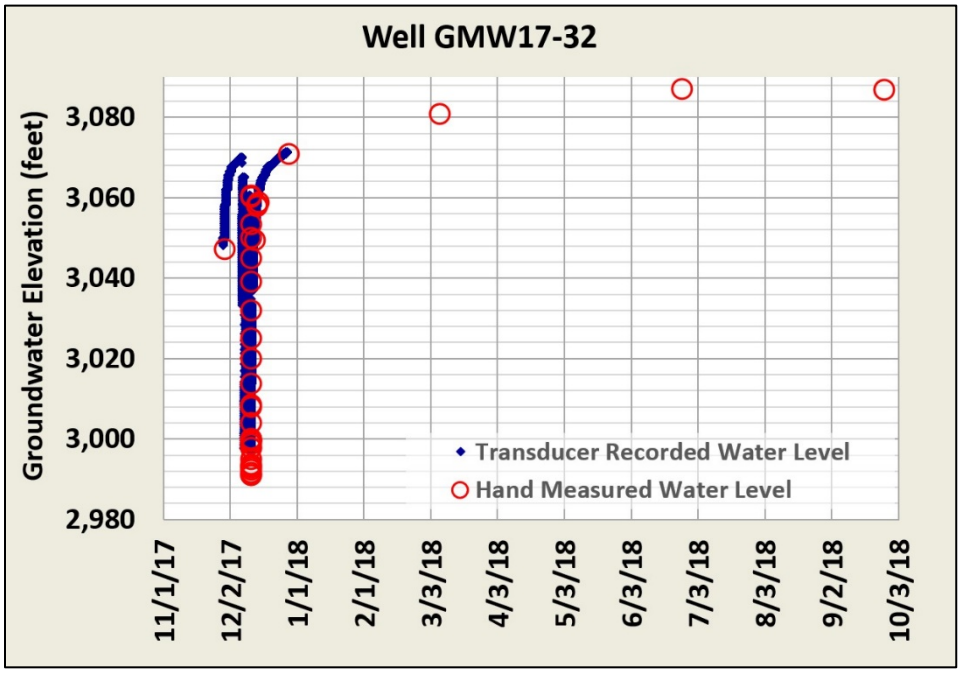

Figure 14. Groundwater hydrograph for GMW17-32

4.2.4 Vibrating Wire Piezometer Water Levels

A total of 15 VWPs were installed in five boreholes during the 2017 Calico mineral resource and reserve program to collect water level data within the deposit area. VWPs were installed predominantly on the eastern side of deposit area at shallow, intermediate, and deep intervals, intended to bracket the reserve ore body (SPF, 2017b). VWP installation was done in accordance with approved standard operating procedures (SPF, 2017a).

Interpretation of the VWP pressure responses (supported by observations of the presence or absence of water during borehole advancement) indicates groundwater occurrence is discontinuous horizontally and vertically within the deposit area. Groundwater is interpreted to be present where positive pressure responses recorded by VWPs are within the sensor accuracy range, greater than approximately 0.4 pounds per square inch (psi). Groundwater is encountered at elevations above, within, and below the deposit area at four of the five borehole locations at various depths: GM17-16-I, GM17-16-D, GM17-20-I, GM17-20-D, GM17-21-I, and GM17-30-I. VWP locations are shown on Figure B-2 in Appendix B, along with individual hydrographs for the six VWPs that encountered groundwater.

Four of the five hydrographs show an abnormal decrease or fluctuations in aquifer pressure at the start of the monitoring period. This is attributed to the construction of the VWPs and residual pressure from the grouting of the bores. Once stabilized, the hydrographs for the VWPs indicate a decrease in aquifer pressure during the start of the monitoring (mid 2017) with a flattening out or slight increase of pressure during the start of 2018. Towards the end of the monitoring (late 2018), there was a continued increase (GM17-20-I and GM17-30-I),

flattening (GM17-16-I and GM17-16-D), and slight decrease (GM17-21-I and GM17-20-D) in aquifer pressures observed. After the initial stabilization of the VWPs, the aquifer pressure fluctuations varied by up to a foot, with no obvious change in water level associated with test pumping the new monitoring wells (GMW17-32, -33) or 59762.

4.2.5 Springs and Flowing Wells

Quarterly flow measurements have been collected from up to 11 baseline springs and one flowing well (Prod-1) between the 1st Quarter of 2013 and the 3rd Quarter of 2018, with the exception of the 1st and 2nd Quarters of 2015. There are sixteen (16) additional springs located within the Study Area that are identified as background springs in the Work Plan. Flow was measured from these background springs and two flowing wells on a twice-yearly basis in 2013, 2014, and 2015.

A list of springs, locations, measurement protocols, and flow data are presented in the groundwater baseline report (SPF, 2021). The location of all the baseline springs is shown on Figure 7.

Overall, flow rates have remained relatively stable over the monitored period, with the following noted exceptions:

- Seasonal influences are apparent at the Deposit Stock Tank location with higher measured flows during winter months (i.e., on the order of approximately 0.4 gpm to 0.6 gpm) and lower flows during summer months (i.e., 0.1 to 0.2 gpm range).
- The flow rate at Lowe Spring was observed to increase to approximately 0.4 gpm following the April 2015 monitoring event.
- Flows at locations including Twin Springs South and Tank East of Negro Rock showed variable rates over time.
- Slightly declining flow rates have been observed at Prod-1, between approximately 0.5 and 1.5 gpm.

The combined flow rates for all of the monitored locations is on the order of roughly 35 gpm to 45 gpm, accounting for temporal variability in the estimated flow rates.

4.3 Geology

4.3.1 Introduction

The aquifer system generally occurs within the Grassy Mountain Formation, described in Abrams (2018) as:

Arkosic sandstones and channel-fill granite clast conglomerates. Mainly white to tan arkosic sandstones. Includes Tgsc, channel fill conglomerates with abundant granite and rhyolite clasts in the upper part of the unit. Uppermost conglomerates locally contain rounded obsidian clasts and rare black chert clasts. Unit Tgs generally becomes finer grained upward and includes white bentonitic clays near the top of the section which, where overlain by unit Tgb often generated large landslide masses. Hot spring activity contemporaneous with the

deposition of the arkoses is indicated by sinter beds Tgsn, and sinter boulders containing silicified reeds and wood near the Grassy mountain gold deposit. Unit Tgs is the host for both the Grassy Mountain and Crabgrass gold deposits.

The Grassy Mountain Formation generally strikes from east to west and dips towards the north. The Grassy Mountain Formation is overlain by Grassy Mountain Basalt south and east of the proposed Grassy Mountain Mine and alluvium in the valley north of the proposed Grassy Mountain Mine. The Grassy Mountain Formation is regionally underlain by Kern Basin Tuff.

4.3.2 Monitoring Well Lithology

The monitoring well network describes the complex aquifer system with a southeast to northwest flow regime:

- To the northeast of the deposit area at PW-1 (refer to Figure 7 for location), the well log describes the water-bearing formation as brown clay and sand and coarse sandstone. The water-bearing zone is overlain by basalt and alluvium. The 2018 water level was 3655 feet msl.
- To the south and west of the deposit area at GW-2 and GW-3, thick beds of clay were encountered to the completed depth of 400 feet. No water was encountered during drilling of either well, but water eventually entered the well. Water levels in 2018 were 3663 and 3402 feet msl, respectively.
- Farther to the southwest of the proposed Grassy Mountain Mine at 59763, the driller encountered tuff and rhyolite to a depth of 324 feet, with no water noted during drilling. The tuff and rhyolite were screened, and water eventually entered the well. The 2018 water level was 3239 feet msl.
- To the west of the proposed Grassy Mountain Mine at GW-6, sand and clay with sandstone were encountered to 340 feet. The 2018 water level was 3236 feet msl.
- To the northwest of the proposed Grassy Mountain Mine at GW-5, tuff was encountered to a depth of 260 feet. The 2018 water level was 3221 feet msl.
- To the north of the proposed Grassy Mountain Mine at Prod-1, the water-bearing zone was sandstone with blue clay to a depth of 425 feet. The 2018 water level was 3436 feet msl.
- Farther to the north at PW-4, layers of clay and sandstone were encountered to a depth of 375 feet, with sandstone being the water-bearing formation. The 2018 water level was 3261 feet msl.

Groundwater typically has been reported in subsurface deposits consisting of unconsolidated or weakly consolidated sandstone and conglomerate units and in siltstone deposits that are interbedded with sandstone and the water levels observed in the wells above are generally representative of southeast to northwest flow. While in general the siltstones, sandstones, and conglomerates of the Grassy Mountain Formation are the water-bearing zones in the vicinity of the proposed Grassy Mountain Mine, these zones do not appear to be continuous across the area and create a heterogenous aquifer system where gradients vary significantly. A table of well completions and a well logs are provided in Appendix F. The following sections

will provide further depictions of how the complex geology around the Grassy Mountain mine and immediate deposit area impacts the flow of groundwater.

4.3.3 Geologic Cross-Sections

In addition to the monitoring wells, there has been an extensive exploratory drilling program in the area of the proposed Grassy Mountain Mine. Lithologic cross-sections (A through G) developed from the monitoring well network and exploratory drilling program using Strater[3] are included as Figure E1 in Appendix E. Minor interpretation connecting the lithology between the bores has been performed for a visual aid to show the possible interconnectivity of the water-bearing zones. Near the deposit area where most of the faulting and rotation occurs, it is likely the beds are dipping steeper than shown on the cross-sections. Encountered water, where noted by the drillers, is shown on the cross-sections. These cross-sections show the spatial variability in the water-bearing materials, and also the variability of encountered water, in the vicinity of the proposed Grassy Mountain Mine.

Cross-section G was created using only bores located near the deposit area with driller-reported water to help show the variability of the water levels and flows. There were multiple bores near this cross-section line that did not note that any water was encountered. Moving downgradient towards Prod-1, GW-4, and PW-4, where there is less faulting and rotation of the beds, there appear two to three coarser-grained zones with more consistent water availability.

Cross-sections H through K were developed to illustrate on a regional scale how geology is affecting the flow of groundwater. Cross-sections H through K only used monitoring well lithology and water level measurements. The potentiometric surface is discussed further in Section 4.6.

The water-bearing zones within the Grassy Mountain Formation are laterally discontinuous as a result of discontinuities due to faults, sedimentary facies changes, and silicification. The horizontal and vertical connectivity between these zones is also limited by, discontinuous interbedded layers of low-permeability clay, siltstone, and sinter. The discontinuities likely promote development of vertical gradients or localized shifts in horizontal gradient that are apparent on the groundwater potentiometric surface maps. This can also be seen in cross-sections I and J in Appendix E. While limited in spatial extent and hydraulic connectivity, the water-bearing zones share the same geological characteristics in that they occur within the Grassy Mountain Formation. In addition, some degree of connectivity is supported by water-level and water-quality data. Taken as a whole, these water-bearing zones are considered to be part of a single, heterogeneous and locally complex aquifer system.

4.3.4 Silicification

In and near the deposit area, most of the sedimentary units are silicified and strongly indurated (Abrams 2018). This silicification is noted in the exploratory drilling logs and the driller's logs

[3] Strater is a well log, bore hole, and cross sectional plotting software created by Golden Software, LLC

for wells near the deposit area (59762, GMW17-31, GMW17-32, GMW17-33, and GMW18-34).

In 2012, a CSAMT survey was conducted by Zonge Geosciences Inc. (Wright, 2012). The CSAMT survey lines were oriented N20°W and located across the area of known mineralization. A total of 18 inverted resistivity sections were developed from the survey data along with interpretive overlays. These sections were used to identify zones of high resistivity in the area of the main proposed Grassy Mountain Mine; the high resistivity is attributed to the highly silicified rocks that host the deposit.

A map of the CSAMT survey data is presented as Figure 15. The survey was completed at four different depth ranges: 0 to 164 feet, 164 to 328 feet, 328 to 656 feet, and 656 to 1,312 feet. Figure 15 generally, shows an increase in resistivity/silicification (white and light blue areas) with depth in the near vicinity of the mine. The area of silicification is centered on the main deposit, with an expanding zone to the north with depth. The darker red and purple areas on the map represent low resistivity/non-silicified sediments. On the 0 to 164 feet map, the white area on the east side is caused by surficial volcanics.

Figure 16 shows the geophysics from 656 to 1,312 feet, the monitoring wells screened in this depth interval, and the exploratory drill holes either completed in this depth interval (if dry) or that encountered water at these depths[4]. The drill holes that encountered water are identified on the map. In general, no water was encountered while drilling holes in the highly silicified area (white area on the map). Some water was encountered in the less resistive (less silicified) areas around the deposit area. The two monitoring wells completed at this depth, GMW17-32 and GMW18-34, encountered minor water and were dry, respectively.

Figure 17 shows the geophysics from 328 to 656 feet and the monitoring wells and drill holes completed at this depth interval. In general drill holes completed in the highly silicified deposit were dry; however, the majority of the drill holes were dry at this depth throughout the area. The drill holes that did encounter water are typically on the periphery of the highly silicified deposit. The monitoring wells completed at this depth in silicified zones are poor producers. PW-1, completed in non-silicified sediments is moderately productive.

Figure 18 shows the geophysics from 164 to 328 feet and the monitoring wells and drill holes completed in this depth interval. In general, the monitoring wells completed in moderately-silicified sediments (GMW17-33) and basalt (59760, 59772) produce at least 10 gpm on a short-term basis. The wells completed in more silicified materials typically produce less than 5 gpm. The drill holes that encountered water were often drilled into less silicified sediments, although some holes completed in silicified zones also encountered water.

Figure 19 shows the geophysics from 0 to 164 feet and the monitoring wells and drill holes completed in this depth interval. GW-1 and 59761, completed in non-silicified sediments and basalt respectively, produce in excess of 50 gpm on a short-term basis. Other monitoring wells completed in more resistive lithology were dry or poor producers. Drill holes generally encountered more water at this depth interval compared to the deeper intervals, with the

[4] The presence and amount of water from the exploratory drilling is based on historical drilling notes.

degree of silicification appearing to have less of an impact on the presence of water. However, most of these holes produced minor amounts of water during drilling.

While the intent of the CSAMT survey was for mineral exploration, the survey is also useful for locating areas of low porosity. From the survey, values of high resistivity can be correlated to low porosity. Porosity, which is a measure of the total pore space in a rock is generally indicative of a rocks ability to transmit water (i.e. permeability). In general, the silicification appears to have a negative effect on porosity and hydraulic conductivity as evidenced by wells and drill holes completed in the zone of silicification. Hydraulic conductivity increases moving away from the deposit area.

Cross-sections with approximate well locations and the CSAMT survey data are provided as Figure 20 and Figure 21. These diagrams help show the relationship between the silicification and water availability. A useful example of where variations in geophysical data indicate differing hydrologic conditions is at GMW17-32 and GMW17-33 (Figure 20). These are in close proximity to CSAMT Line 10. GMW17-33 is screened at a higher elevation than GMW17-32 where geophysical data indicates a higher porosity, while GMW17-32 is screened deeper in a zone of low porosity. Test pumping of GMW17-33 suggests a relatively isolated zone of higher porosity material that was dewatered during testing. Test pumping GMW17-32, however, confirms the presence of an aquifer with very low transmissivity. Pumping test for these wells is discussed further in section 4.8.

Another example of the geophysical data accurately representing geologic conditions is presented in Figure 21. This Figure provides a comparison of formation resistivity values and well lithology for GMW17-32 and GMW18-34 along CSAMT line 11. This example is representative of how lithology and silicification affect groundwater flow. Higher elevations at GMW18-34 indicated higher porosity for coarse-grained sediments and lower porosity for finer grained sediments. In GWM17-32, a large section of coarser grain sediments corresponds to an area of higher porosity. The geophysical data is also representative of hydrologic conditions as GMW18-34 is located in an area with an overall lower porosity and this well has been reported as dry since its completion. In contrast, GMW17-32 is located in an area of relatively higher porosity and water was reported after completion.

Of note is that water was encountered during drilling of GMW17-32 at a depth of 235 feet in an area of apparent higher porosity. The highly silicified areas do not appear to be water-bearing. Using the information gained from these cross-sections, maps, and drilling of GMW18-34, it is apparent the large section of the silicified formation upgradient and encompassing the deposit area is an impediment to groundwater flow through the proposed Grassy Mountain Mine.

4.4 Groundwater Occurrence within the Proposed Grassy Mountain Mine

4.4.1 Water Encountered During Drilling

The proposed Grassy Mountain Mine consists of highly silicified sediments of the Grassy Mountain Formation. The proposed Grassy Mountain Mine lithology is described by Abrams (2018):

Silicification in the form of sinters and disseminated quartz is a prominent alteration type at Grassy Mountain and is largely controlled by hot-spring vents. Silicification occurs both pervasively as silica flooding, and as cross-cutting veins and stockworks. The silicified envelope has plan dimensions up to 3,000 feet (north-south) by 2,500 feet (east-west). Silicification is surrounded by widespread, barren, clay-rich (20- to 40-percent montmorillonite), tuffaceous siltstone and arkose with minor disseminated pyrite. Many of the sinters occur as sheets instead of mounds, which suggest that they are related to vents along faults rather than point sources.

The presence and quantity of groundwater within the deposit area can be described based on water reported during exploratory drilling, monitoring well construction and testing, and VWP water level data.

Figure 22 shows the proposed Grassy Mountain Mine, drill holes, monitoring wells, and piezometers. The holes with reported water are noted, with depth, elevation, and quantity of

water as observed by the well driller. The quantity of water refers to flow of water air-lifted from the hole during drilling; there is not an indication of duration of flow in the driller notes. In the deposit area, most of the drill holes did not encounter water. Of the holes that did encounter water, flows were less than 25 gpm and often from a depth of more than 800 feet (below an elevation of 3,000 feet). When drill holes encountered water outside the deposit area, higher flows in excess of 50 gpm are noted, generally east of the proposed Grassy Mountain Mine. This area is typically less silicified and it is also possible that the Badger and Schweizer faults act as barriers to groundwater flow, resulting in a mounding of water on the east and south sides of the proposed Grassy Mountain Mine. Higher well yields are likely associated with less silicified materials.

Figure 22 also includes the monitoring wells in the immediate vicinity of the deposit area, with elevation of the screened interval and short-term production noted. The deeper wells screened below an elevation of about 3,200 feet are dry or poor producers. GMW17-33 is a moderately productive well; the well was test pumped at an average rate of 28 gpm for about 2 days before a negative boundary caused the pumping water level to reach the pump. Additional information is provided in Section 4.8.2.3.

A more regional picture is provided in Figure 23 which represents well yield relative to fault location. Here it is evident that the most productive locations are generally to the east of the Grassy Mountain Fault zone as mapped in Abrams, 2018.

A plot of flow verses depth where water was encountered for drill holes within approximately 1,500 feet of the center of the proposed Grassy Mountain Mine is provided as Figure 24. There were a few drill holes that noted the presence of water that are not included in this figure as no quantity of water was recorded. There were two drill holes, 026-078 and 026-094, where the notes stated “drowning hammer” and “lots of water”. For these holes, a flow rate of 100 gpm was used just to provide a value representing the described quantity of water. Figure 24shows that there is not an obvious relationship between water produced from drill holes and depth where water was encountered. A plot of flow versus elevation (Figure 25) also does not show a relationship. This supports the notion of a complex heterogeneous aquifer system, influenced by silicification, faulting and steeply dipping beds of siltstone, clay, and sinter. The expected depth of the proposed mine is approximately 3,050 feet.

4.4.2 Static Water Levels

A map showing drill holes, monitoring wells, piezometers, and VWPs with static water levels[5] is provided as Figure 26. The map also includes the faults mapped by Calico geologists. Based on the available information, static water levels range from 3,300 feet to 3,100 feet within the deposit area. However, most of the VWPs (9 of 15) do not indicate the presence of water. None of the VWPs installed above a depth of 3,150 feet have detected water. Of the nine sensors installed below a depth of 3,150 feet, six have detected water. Measured data are presented in Figure 27.

There are at least 90 holes drilled below an elevation of 3,100 feet within the proposed Grassy Mountain Mine, and only four reportedly produced water during drilling. The expected maximum depth of the proposed mine is approximately 3,050 feet. Available information suggests that the proposed Grassy Mountain Mine is likely saturated at various depths below an elevation of 3,300 feet. However, the silicified nature of the proposed Grassy Mountain Mine and resulting very low hydraulic conductivity appears to severely restrict groundwater flow. It is also likely that the numerous faults within and near the proposed Grassy Mountain Mine act as barriers to groundwater flow particularly on the south and east sides. Static water levels in the immediate vicinity of the deposit area range from an elevation of about 3,600 feet to 3,100 feet, with water levels appearing to be strongly influenced by vertical gradient, as discussed in Section 4.6.1. The monitoring well GMW18-34, drilled to a depth of 950 feet (3003 feet msl) and located up-gradient of the deposit area, did not encounter water during drilling in the spring of 2018, and no water has been detected in the well since then.

4.4.3 Cross-Sections

Several representative cross-sections through the proposed Grassy Mountain Mine have been developed based on drill hole lithology and the mine block model developed by Mine Development Associates (MDA 2018). The cross sections show the drill holes and depth where water was encountered and the drill holes where the VWPs were installed and the resultant static water level. These cross-sections are included in Appendix E.

The cross-sections demonstrate the sporadic nature of water encountered, suggesting that while likely saturated below an elevation of 3,300 feet, groundwater flow is severely restricted by low hydraulic conductivity as a result of silicification, faults, and steeply dipping interbedded sedimentary facies changes. Another factor that affects the lack of water in the proposed Grassy Mountain Mine is the limited recharge area contributing groundwater to the deposit (refer to Section 4.9.1).

Groundwater occurrence is variable, both laterally and vertically within the ore body, at elevations ranging from 3,500 feet to 2,800 feet with the encountered water-bearing zones mainly downgradient of the majority of the faulting and mainly in the arkose. Because groundwater flow is hindered by faulting and silicification upgradient and within the deposit area, the primary source of groundwater found on the downgradient side of the proposed Grassy Mountain Mine may be immediate local recharge. Boreholes that encountered groundwater within the deposit area found limited amounts, on the scale of less than 20 gpm based on driller's reports (Figure 25).

Groundwater elevations measured within the deposit area are often deeper than groundwater elevations measured immediately outside the deposit area. The deeper groundwater elevations, and associated large vertical gradients, are related to the geology of the proposed Grassy Mountain Mine. Specifically, decreased hydraulic conductivity associated with silicification, and the compartmentalization created by faulting, impedes groundwater flow into the proposed Grassy Mountain Mine from adjacent and upgradient portions of the Grassy Mountain Formation. Thus, the rate of groundwater flow into the proposed Grassy Mountain Mine is believed to be much less than the rate of flow through the permeable zones of Grassy Mountain Formation surrounding the proposed Grassy Mountain Mine. These same geologic mechanisms, silicification and faulting, might have a different effect on the underlying Kern Basin Tuff, however. If the vertical hydraulic conductivity of the Kern Basin Tuff beneath the proposed Grassy Mountain Mine is maintained, or even increased by silicification and fracturing, then vertical flow from the Grassy Mountain Formation into (and potentially through) the Kern Basin Tuff could be proportionately greater within the proposed Grassy Mountain Mine than in areas outside the proposed Grassy Mountain Mine. In such a scenario, the Kern Basin Tuff beneath the proposed Grassy Mountain Mine could function as a partial drain for the small amount of groundwater flow that enters the proposed Grassy Mountain Mine. This drainage effect would create the lower groundwater elevations found within deep portions of the proposed Grassy Mountain Mine.

4.5 Groundwater Elevation and Well Depth

A plot of completion depth (well screen midpoint elevation) versus groundwater elevation for wells (shown in blue circles) and VWPs (shown in orange triangles) near the deposit area is shown as Figure 28. Groundwater elevation is strongly correlated with screen depth in this area. Figure 28 suggests an aquifer system with strong vertical gradients (i.e. deeper wells have deeper water surface elevations). Vertical gradient within the aquifer system is discussed in more detail in Section 4.6.1.2.

If the completion depth of all monitoring wells is plotted against groundwater elevation (Figure 29), the correlation is not as strong, indicating less of an influence of vertical gradient in the overall area. Finally, if the plot only includes the wells with completion depths greater than 50 feet and located downgradient of the proposed Grassy Mountain Mine (Figure30), the correlation is even weaker, with wells constructed across a range of elevations exhibiting similar water surface elevations. The downgradient water level data suggests a single aquifer system, with a consistent piezometric surface (i.e., wells that are completed at different elevations show relatively consistent aquifer pressure). These wells are not affected by aquifer silicification, and vertical gradients are not as pronounced. In general, the plots of completion depth versus groundwater elevation suggest a single aquifer system, with high vertical gradients near the deposit area. The overall concept of a single aquifer system has been posed by previous investigations (JMM 1991, ABC 1992).

4.6 Potentiometric Surface

Potentiometric surface maps are two-dimensional depictions of groundwater flow. In reality, groundwater flow occurs in three-dimensions. These maps, however, are useful for providing an indication of the overall, general groundwater flow direction and hydraulic gradient. This section describes the potentiometric surface of the aquifer system near Grassy Mountain. The potentiometric surface reflects a single aquifer system that is supported by geology, water quality, potentiometric surface, and water level data.

Groundwater elevation (potentiometric surface) contour maps have been developed using the annual average water level data from 2013 through 2017 and for each quarter in 2017 (Vol 1 Appendix E). With additional water level data from monitoring locations completed in late 2017 and early 2018, contours were also developed for average water levels in 2018. This includes water level measurements from new monitoring wells (GMW17-31, GMW 17-33, and GMW18-34) and VWPs (GM17-16, GM17-20, and GM17-21). In areas where there are "clustered" wells (GMW17-32/GMW17-33 and 59762/GMW17-31), shallower water levels

were used to created contours. These maps were created using the two-dimensional mapping software utility Surfer® (Version 8) and are presented in the groundwater baseline report (SPF, 2021a). The potentiometric surface map created using 2018 water level data is provided in this report as Figure 31. This map is considered representative of groundwater flow in the vicinity of the proposed Grassy Mountain Mine. In addition to recently measured water levels, the 2018 contour surface incorporated static water levels from drill holes to provide the most accurate representation of aquifer conditions. Due to the consistent lower water level elevations in the deposit area with observed water levels between 3,100 and 3,300 feet msl, a single control point was added in the western portion of the deposit area for the 2018 contours. Review of the groundwater potentiometric surface suggests the following.

- The groundwater level data available for 2013 through 2017 indicate the potentiometric surface has remained relatively constant over the period of monitoring, generally without apparent seasonal influences. There are a few wells that do appear to be influenced by winter and spring precipitation, but these are either shallow wells (59768) or wells completed in fractured basalt near a seasonal water impoundment (59760, 59761, and 59772). The consistent potentiometric surface reflects stable groundwater level trends measured in individual wells over time, coupled with a relatively high gradient that overwhelms any influence of minor water level fluctuations. These contours do not account for lower groundwater elevations measured in the deposit area. Water levels are represented at an elevation of approximately 3,600 ft msl.

- Groundwater flow generally occurs from the southeast to the northwest in the vicinity of the Project, from higher elevations along the base of Grassy Mountain (~4,000 feet amsl) to lower elevations along Negro Rock Canyon (~3,200 feet amsl). The groundwater elevations range from approximately 3,700 feet amsl (at well 57-1 southwest of the proposed Grassy Mountain Mine) to approximately 3,220 feet (at well GW-5 northwest of the proposed Grassy Mountain Mine).

- Contours for average water level conditions in 2018 (Figure 31) show local variations are apparent in the potentiometric surface, attributed to structural and/or spatial contrasts in aquifer permeability distribution and vertical gradients possibly due to silicification. For example, steeper horizontal hydraulic gradients are apparent between wells upgradient of the deposit area (59760, 59772) and water level measurements made in the highly silicified mine area. Upgradient water levels are >3,670 ft msl and water levels in the deposit area are between 3,100 and 3,300 ft msl. In the 2018 contours, the direction of groundwater flow is still to the northwest, but there is a potentiometric depression within the deposit area. In the contours for 2013 to 2017 when much of the data in the deposit area was not available, there appeared to be a continuous downward gradient from 59772, ~3670 ft msl (completed from a depth of 165-205 ft [3603-3563 ft msl]) to GW-3, 3400 ft msl (completed from a depth of 320-350 feet [3314-3284 ft msl]). In the

deposit area, the high degree of silicification (Figures 14 through 18) has created very low conductivity which significantly inhibits groundwater flow in this area. The potentiometric surface in Figure 31 reflects the aggregate impact of structural and lithologic variation.

- GMW18-34 was drilled in 2018 with a completion interval of 830 to 890 feet [3127-3067 ft msl]. This well was drilled in the upgradient side of the deposit area and has been reported as dry since its completion. The lack of water in this well an indication of very low hydraulic conductivity in the silicified area of the deposit.

- Wells GMW17-32 and 59762, and drill hole and VWP data support the conclusion of a lower water level surface in the deposit area. The groundwater elevations for these wells range from approximately 3,150 feet amsl at the proposed Grassy Mountain Mine to approximately 3,100 feet at the two monitoring wells just northwest of the proposed Grassy Mountain Mine.

- It is worth noting that the only deep monitoring wells (GMW17-32 & 59762) in the network are completed near the deposit area and that other nearby monitoring wells completed at similar elevation (approximately 3,000 to 3,100 feet), including PW-4, GW-4, GW-6, and 59770, all have static water elevations more than 100 feet higher than the deep wells. Due to the significant compartmentalization of the aquifer near the deposit area from the silicification, faulting, and steeply dipping sedimentary beds, the vertical gradient is increased.

- Due to the high heterogeneity and fracturing in the deposit area and an apparent lack of connectivity of the fractures, there are likely pockets of water above the potentiometric surface represented in Figure 31.

- Down gradient and northwest of the deposit area, wells 59766 (completion interval 25 to 45 feet [3435-3415 ft msl]) and 59768 (completion interval 10 to 25 feet [3471-3456 ft msl]) are completed in shallow unconfined sandstone sections of the aquifer. 59768 is located further north of the project closer to Prod-1 where the aquifer water level is above ground surface. The static water level of 59768 fits in well with the water level contour map. 59766 has a relatively shallower water level than the nearby deeper completed wells causing the upgradient contour lines to bend in its direction. It is likely this well is completed in a semi-perched section of the aquifer created by faulting or discontinuous confining layers from which water flows to the underlying water bearing zones and some of the surfaces to the northwest at the spring called Tank East of Negro Rock. Along with 59766, BLM and GW-3 have elevation water levels that bend water level contours down gradient. Each of these wells are located along the same fault (Figure 29). This fault has been highlighted as a potential conduit for groundwater flow.

- Another area where faulting effects the flow of groundwater occurs at 59763, 59764, and GW-6. These wells are just to the west of the fault identified as a potential conduit. Here water levels lower elevations in the area of these wells create a trough parallel to the direction of groundwater flow.
- With increasing distance to the northwest from the deposit area, there is a much less pronounced gradient. The more gradual gradient is likely due to higher permeability associated with decreasing influence of silicification.

- The potentiometric surface in Figure 31 is also represented in cross sections H through K in Appendix E. These figures represent how the single aquifer system is affected by the faulting and silicification near the mine deposit. Near the mine, significant horizontal gradients are present (GMW17-32 and GMW-33 in Cross-Section I) and with increasing distance from the mine, water levels mirror topography with a consistent gradient.

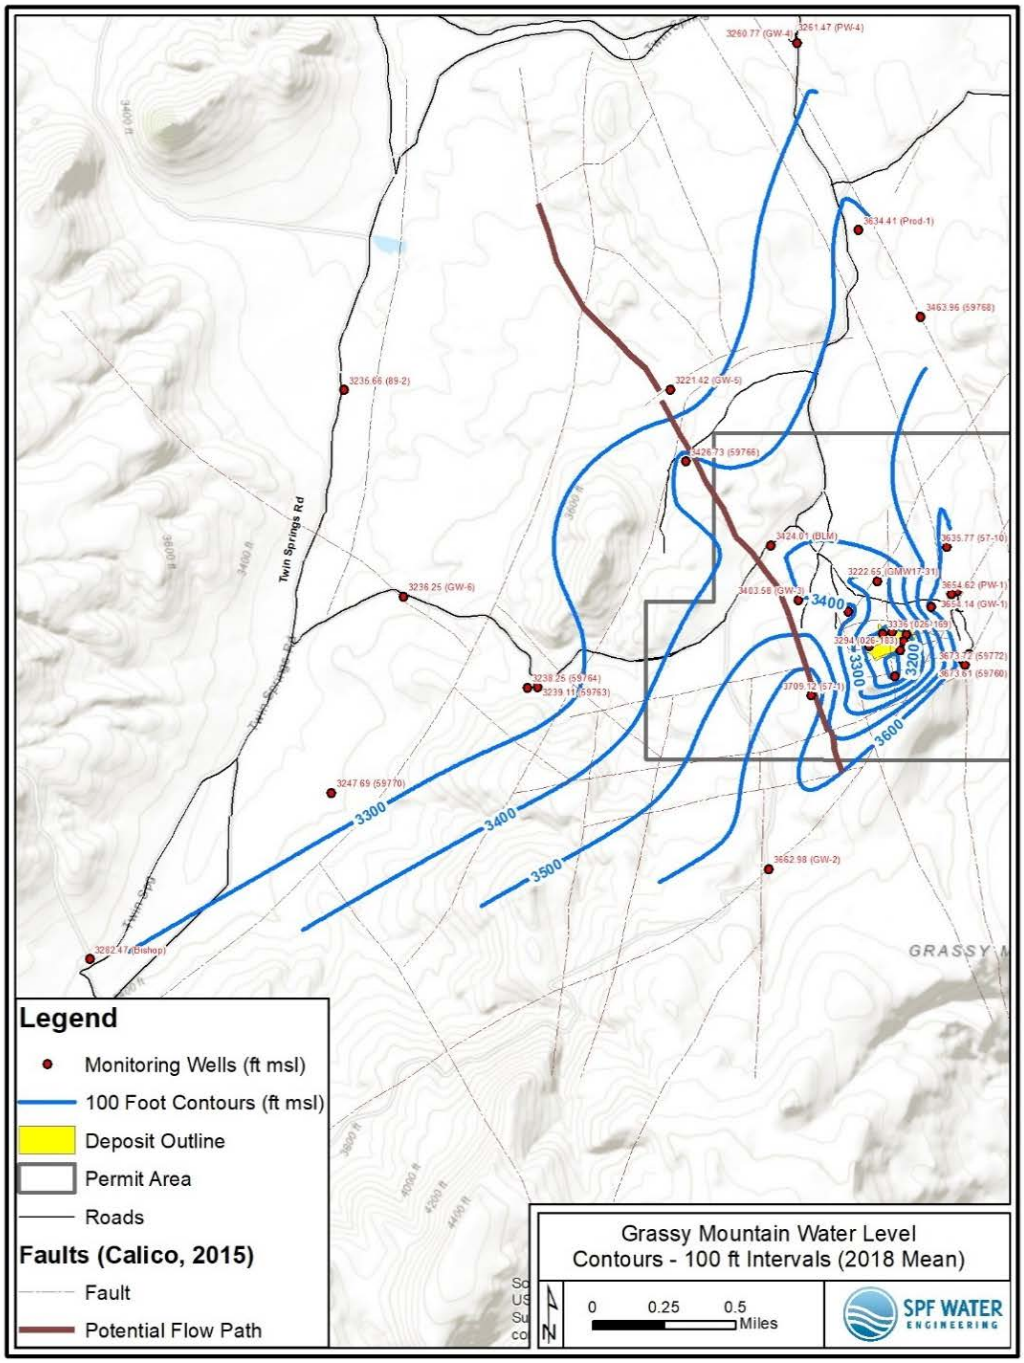

Figure 31. Potentiometric surface based on shallow wells (average 2018 conditions)

4.6.1 Hydraulic Gradients

4.6.1.1 Horizontal Hydraulic Gradients

The horizontal hydraulic gradient is calculated from the change in groundwater elevation over distance between two locations. The hydraulic gradient is a manifestation of flow resistance; higher gradients are an indication of higher resistance to groundwater flow. With the exception of the deposit area, the shallow potentiometric surface generally shows a relatively high and somewhat uniform horizontal hydraulic gradient in the hilly area to the southeast and a flatter gradient toward the north and northwest. In the southeast area, the high gradients are most likely the result of low hydraulic conductivity and a lack of connectivity. The steep topography may also be a contributing factor. The gradient lessens to the north and northwest where aquifer permeability increases and the topography is flatter. This general conclusion is also reported in ABC, 1992.

As shown in Table 3 for average 2016 water level conditions from the shallow monitoring wells, the hydraulic gradient varies considerably across the area, ranging from approximately 0.0001ft/ft (between wells GW-6 and 89-2) in the basin to 0.18 ft/ft (between wells 57-1 and GW-3) near the deposit area.

Steeper gradients (i.e., between wells 57-1 and GW-3 and wells 59766 and GW-5) are mainly attributed to contrasting permeability (or transmissivity) zones that reflect a transition between areas of lower to higher permeability. Section 4.3.4 presents geophysical evidence that silicification may contribute to differences in permeability. Higher silicification results in lower permeability. Faulting in the vicinity may also contribute, but the data presented in this report support that faults have varying behavior within the study area (i.e., flow conduits or barriers, or no obvious effect on horizontal gradient; the influence of faults on groundwater flow is discussed in Section 4.7).

The area surrounding wells 59766, BLM, and GW-3, conversely suggests a localized hydraulic gradient from northwest to southeast that is influenced by the depth of the completion intervals. However, these wells are completed at significantly different depths with GW-3 having the deepest screened interval and 59766 the shallowest. With the regional vertical gradient in the Study Area consistently and strongly downward, the progressively deeper screens for these three wells going from northwest to southeast cause the gradient direction in this area to appear to be reversed from the overall trend, with a higher groundwater elevation at well 59766 (3,437 feet) compared to the BLM well (3,423 feet) and GW-3 well (3,406 feet).

Well	Average 2016 Groundwater Elevation (ft amsl)	Approximate Horizontal Distance, dl (ft)	Approximate Groundwater Elevation Difference, dh (ft)	Horizontal Hydraulic Gradient (dh/dl)
57-1	3,702.14	1,625	296	0.18
GW-3	3,406.57			
59766	3,427.47	1,385	206	0.15
GW-5	3,221.12			
GW-2	3,663.01	5,425	424	0.08
59763	3,239.35			
GW-6	3,236.38	3,920	1	0.0001
89-2	3,235.83			
59766	3,427.47	3,432	21	0.006
GW-3	3,406.57			

Table 3. Horizontal hydraulic gradients (average shallow 2016 conditions)

4.6.1.2 Vertical Hydraulic Gradients

The vertical hydraulic gradient is calculated from the change in groundwater elevation over difference in well completion depth. The vertical hydraulic gradients for select pairs of wells presented in Table 4 and Table 5 were calculated by dividing the difference in groundwater elevation by the vertical distance between well screen midpoint elevations[6].

Table 4 utilizes average 2016 conditions for four well pairs that are not within the close vicinity of the deposit area and therefore not as influenced by silicification. Overall, downward (positive) vertical hydraulic gradients (10^{-2} to 10^{-3} range) are present throughout the area. This trend is consistent with areas that receive recharge associated with higher topography, such as Grassy Mountain. The well pair 59763/59764 suggests a vertical hydraulic gradient with an upward trend (shown as a negative value in Table 4 below). 59763 is completed in fractured volcanics while 59764 is completed in sandstone. Such a variance in lithology in wells only 150 feet apart indicates possible faulting between the two wells. These wells are located hydraulically downgradient of the deposit area.

[6] In instances where multiple screens are present in a well (i.e., PW-1 and PW-4), the highest screen interval was selected.

Well	Average 2016 Groundwater Elevation (ft amsl)	Screen Midpoint Elevation (ft amsl)	Approximate Vertical Distance, dl (ft)	Approximate Groundwater Elevation Difference, dh (ft)	Vertical Hydraulic Gradient (dh/dl)
PW-4	3,261.06	3,051	23	0.43	0.02
GW-4	3,260.63	3,028			
GW-1	3,653.98	3,563	184	1.03	0.006
PW-1	3,652.95	3,379			
59761	3,672.64	3,655	76	0.12	0.002
59760	3,672.52	3,579			
59763	3,239.35	3,211	-11	0.76	-0.07
59764	3,238.59	3,222			

Table 4. Vertical hydraulic gradients (average shallow 2016 conditions)

Table 5 presents vertical hydraulic gradients between shallow and deep zones within the silicified area at the proposed Grassy Mountain Mine. Each of these paired wells were drilled approximately 50 feet apart. The estimated vertical gradient in this area is downward and quite steep, an average of 0.95 between the two pairings. The aquifer near the proposed Grassy Mountain Mine has a much higher vertical gradient than the aquifer downgradient of the proposed Grassy Mountain Mine; This steeper gradient appears to be related to a lack of fracture connectivity caused by silicification, faulting, and steeply dipping beds. The high vertical gradient is also evident in Figure 28 in Section 4.5 that shows that water level elevation is closely related to the depth of completion near the deposit area.

Well	Groundwater Elevation (9/2018), ft amsl	Screen Midpoint Elevation (ft amsl)	Approximate Groundwater Elevation Difference, dh (ft)	Approximate Screen Elevation Difference, dl (ft)	Vertical Hydraulic Gradient (dh/dl)
GMW17-31	3,227.59	3246	-124	-119	1.0
59762	3,103.40	3127			
GMW17-33	3,458.00	3413	-371	-407	0.9
GMW17-32	3,087.10	3006			

Table 5. Shallow to deep vertical gradients near deposit area (9/26/2018)

4.7 Fault/Structural Influence on Groundwater Flow

The proposed Grassy Mountain Mine is located within an interpreted horst block, structurally affected by complex block faulting and rotation (Abrams 2019). From a two-dimensional perspective, faults regionally appear to act as partial barriers to groundwater flow. Figure 32 shows drill hole and monitoring well water production data and faults. There are typically higher producing wells south and east of the Badger and Schweizer faults and north of the Cherokee and Coyote faults.

The geologic cross-sections provided in Appendix E also provide insight into the effect of faulting on the presence of groundwater in the local vicinity of the proposed Grassy Mountain Mine. These cross-sections help visualize the degree of compartmentalization caused by the significant number of intersections between the faults and lower permeable sedimentary facies (clay, sinter, and siltstone). This is especially evident in cross-section I in Appendix E where water levels indicate that significantly large gradients are present near the mine area. The contour surface represented in cross-section I is based on the water level observed in GMW17-33 which is significantly shallower than the water level in GMW17-32. In the immediate vicinity of the deposit, the horizontal gradient becomes even steeper based on VWP and drill hole data. The sections also show the inconsistent nature of the encountered water during drilling.

Even with the faults in the Study Area generally acting as low permeability barriers in the sandstone and arkose, there is evidence for this same faulting to be the cause of increased permeability into the underlying tuff. The increase in the welding of the volcanic tuff in near the proposed Grassy Mountain Mine due to the geothermal activity likely caused the tuff to become more brittle, increasing fracturing during faulting. With significantly more faulting in the deposit area compared to the rest on the study area in combination with a welded brittle tuff, it is possible the deeper groundwater is draining into the underlying tuff. With such a small amount of water being able to flow to the deep area under the silicified zone, it is likely a fractured tuff would be able to have a high enough hydraulic conductivity to drain this water.

Where measurable groundwater is encountered within the deposit area (Figure 22), it is certainty possible that local faults along with localized fracturing may serve as conduits for flow; but available evidence indicates that the degree to which this occurs is limited. A potential example of this would be the relatively high rate of production (~50 gpm) at drill hole 026-097 located on the southeast side of the Badger Fault versus the occurrence of mostly dry drill holes on the northwest side of the Badger Fault.

On the regional scale, the Grassy Mountain fault zone, which includes the Schweizer fault, extends north of the proposed Grassy Mountain Mine (RQV 2015) (Figure 22). This fault zone appears to restrict lateral groundwater flow, serving as a negative hydraulic boundary (JMM, 1991). This fault zone is presumed to have been detected in test pumping of production wells PW-1, Prod-1, and PW-4, refer to Section 4.8.The most productive wells in the vicinity of the

proposed Grassy Mountain Mine are located along this fault zone; with higher groundwater flows on the east side.

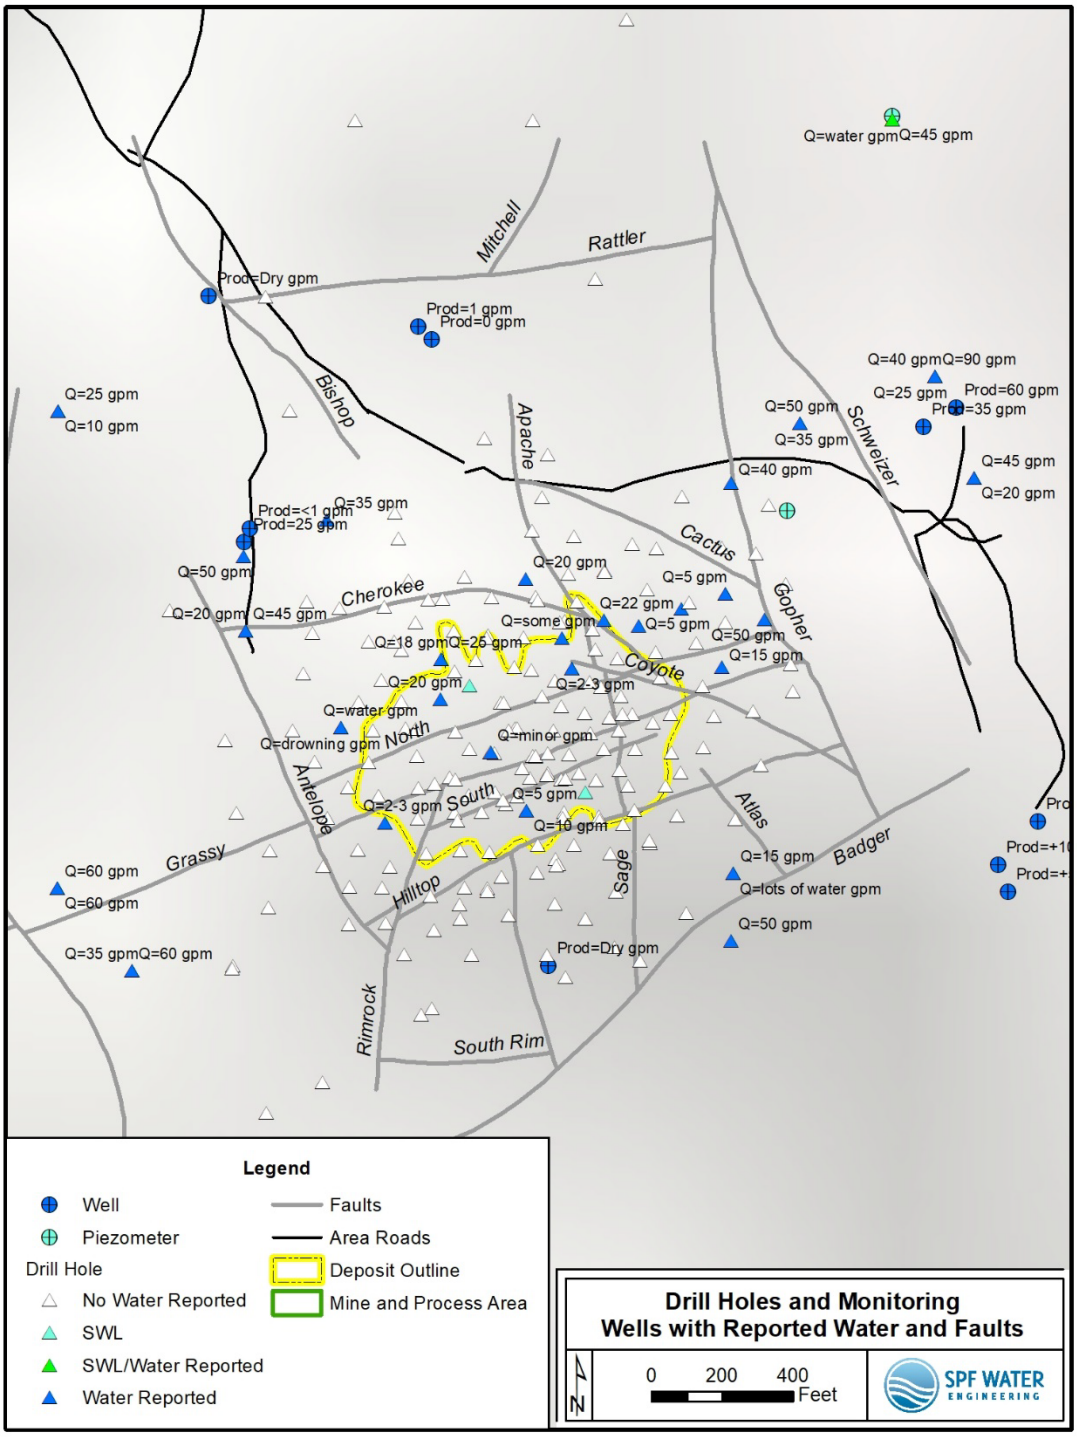

Figure 32. Drill hole and wells with water data and faults

4.8 Hydraulic Properties

Aquifer hydraulic properties in the vicinity of the proposed Grassy Mountain Mine were estimated from aquifer pumping tests conducted during the late 1980s and early 1990s and more recently on 59762, GMW17-32 and GMW17-33 in 2017. The latter wells are located near the deposit area.

The majority of wells installed within the Grassy Mountain vicinity appear to be completed within confined to semi-confined aquifer conditions, with increasingly confined conditions at depth. This designation is based on observed lithologic conditions documenting the occurrence of discontinuous, alternating confining layers (i.e., unconsolidated silt and clay zones and consolidated sedimentary and bedrock deposits) noted on well logs.

4.8.1 Historical Pumping Tests

Table 6 provides the estimated hydraulic conductivity and transmissivity based on historical test pumping of Prod-1, PW-1, PW-4, and Bishop (Rye Field). The estimated hydraulic conductivity values on the order of 10^{-3} cm/s to 10^{-5} cm/s (0.03 ft/d or 3 ft/d) are within the range of expected values for sandstone and conglomerate aquifers (Freeze and Cherry, 1979).

Transmissivity estimates based on the pumping tests are summarized below (JMM, 1991):

- Prod-1, tested at 100 gpm, ranged from 1,500 gpd/ft near the well, and decreased to 200 gpd/ft after 800 minutes of pumping.
- PW-1, tested at 30 gpm, ranged between 100 and 250 gpd/ft.
- PW-4, tested at 145 gpm, ranged from 3,700 gpd/ft near the well, and decreased to 1,800 gpd/ft after 1,000 minutes of pumping. Aquifer storativity was estimated at 8.5×10^{-5}.
- Bishop (Rye Field), tested between 14 and 25 gpm, ranged from 250 gpd/ft near the well to 150 gpd/ft after 30 minutes of pumping.

The decline in transmissivity observed during test pumping of Prod-1, PW-1, and PW-4 was attributed to one or more negative hydraulic boundaries; the boundaries might be attributable to local thinning of the aquifer, faulting, or decreasing aquifer permeability (JMM, 1991).

A confined aquifer type in the vicinity of PW-4 is supported by an estimated storativity on the order of 8.5×10^{-5} calculated from testing of well PW-4 and monitoring of nearby GW-4. Confined aquifers typically have storativity values in the range of 0.005 to 0.00005 (Freeze and Cherry, 1979).

Testing of these wells indicates that hydraulic conductivity increases moving north, away from the proposed Grassy Mountain Mine (PW-1 is closest to the proposed Grassy Mountain Mine, PW-4 is farthest away). The low hydraulic conductivity near the deposit area may be due to silicification of the sedimentary rocks (JMM, 1991).

Well	Date	Test Type	Reported Estimated Hydraulic Conductivity (cm/s)	(Low) Estimated Hydraulic Conductivity (ft/d)	(High) Estimated Hydraulic Conductivity (ft/d)	Estimated Screen Elevation (ft amsl)	Screened Lithology (Drillers Report)
Prod-1	1/14/1991 - 1/16/1991	Constant Rate	10^{-4} - 10^{-5}	0.03	0.3	3,291-3,181	Sandstone with blue clay
						3,111-3,081	Sandstone with blue clay
						3,056-3,016	Sandstone (hard with fractures)
PW-1	1/29/1991-2/5/1991	Constant Rate	10^{-5}	0.03		3,389 - 3,369 3,309 - 3,289	Brown clay and sand Sandstone
PW-4	11/28/1989-12/5/1989	Constant Rate	10^{-3}	3		3,061 - 3,041	Sandstone
						3,001 - 2,981	Sandstone and conglomerate

Table 6. Estimated hydraulic conductivity from pumping tests (adapted from ABC, 1992)

4.8.2 Pumping Tests Performed in 2017 & 2019

Aquifer pumping tests were performed during 2017 on selected wells (59762, GMW17-32, and GMW17-33). These wells were selected based on their proximity to the mine. Prior to this work, there were no known aquifer testing data in close proximity to the deposit. Pumping test results for each well are summarized in Table 7.

Well	**Date**	**Test Type**	**(Low) Estimated Hydraulic Conductivity (ft/day)**	**(High) Estimated Hydraulic Conductivity (ft/day)**	**Screen Elevation (ft msl)**	**Screened Lithology (Drillers Report)**
57962	12/6/2017	Constant Rate	0.0035	0.02	3175-3065	Clayey siltstone and silicified siltstone
GMW17-32	12/11/2017	Variable Rate	0.0004	0.003	3026-2986	tuff, arkose, siltstone, and clay
GMW17-33	12/14/2017 - 12/18/2017	Variable Rate	0.2	0.4	3465-3365	sinter and silicified siltstone

Table 7. Estimated hydraulic conductivity from pumping tests performed in 2017

4.8.2.1 59762

Well 59762 was installed in 1993 to a depth of 657 feet bgs and screened from 537 feet 657 feet bgs in clayey siltstone and silicified siltstone based on the driller's report. The measured depth to groundwater in the well has ranged from 619 to 621 feet bmp in quarterly measurements taken since 2013 (Figure 13).

Well 59762 was tested on December 6, 2017, at an average pumping rate of approximately 1 gpm for 2 hours. Excessive drawdown in the well to near the pump intake prohibited longer-term testing. The static (pre-pumping) water level was 627.91 feet bmp[7]. The measurement point was approximately 0.73 feet above the 4-inch well casing. The pump intake was set at 655 feet below the reference point. The total drawdown in the well at the end of the pumping period was approximately 23 feet. No wells in the vicinity appeared to respond to pumping at Well 59762.

Transmissivity was estimated using the Cooper-Jacob non-equilibrium equation[8] (Driscoll, 1986) by plotting the elapsed pumping time on a semi-log plot with drawdown (Figure 33). Straight-line trends are not apparent on the plot for Well 59762, indicating flow to the well is not strictly two-dimensional and radial. The estimated transmissivity during the initial period of testing (approximately 40 minutes) was 33 gpd/ft (or 4 ft^2/d). An apparent negative boundary was encountered, based on increased drawdown effects, decreasing the transmissivity to approximately 15 gpd/ft (2 ft^2/d). Transmissivity estimates are based on projecting straight-line trends beyond the period tested due to the short duration of testing and apparent boundary effects. These transmissivity estimates are considered to be an over-estimate, as they do not account for casing storage.

Transmissivity is the product of the hydraulic conductivity and saturated thickness of the aquifer. The saturated aquifer thickness extends from the groundwater table to the base of the aquifer. Based on previous investigations (JMM, 1991 and ABC, 1992), the saturated aquifer thickness is estimated at 200 to 300 feet in the Grassy Mountain vicinity. The actual saturated thickness may be more or less depending on the degree of hydraulic continuity, especially since some regions of the aquifer may behave as compartmentalized zones. The estimated hydraulic conductivity near Well 59762 would be approximately 0.02 ft/d, assuming an average saturated aquifer thickness of 200 feet for the area. The overall hydraulic conductivity may be less based on unsustainable pumping rates, excessive drawdown effects, and expected trends over a longer period of pumping.

[7] The field measured water level in the well on November 29, 2017, prior to well development or pumping activities, was 620.63 feet below the measurement point. The measurement on December 6th before testing likely represents a recovering water level following well development (bailing) efforts.

[8] The Cooper-Jacob method is based on simplifying assumptions (i.e., the aquifer is uniform in extent, the well is 100 percent efficient, among other assumptions) that may not necessarily reflect actual field conditions.

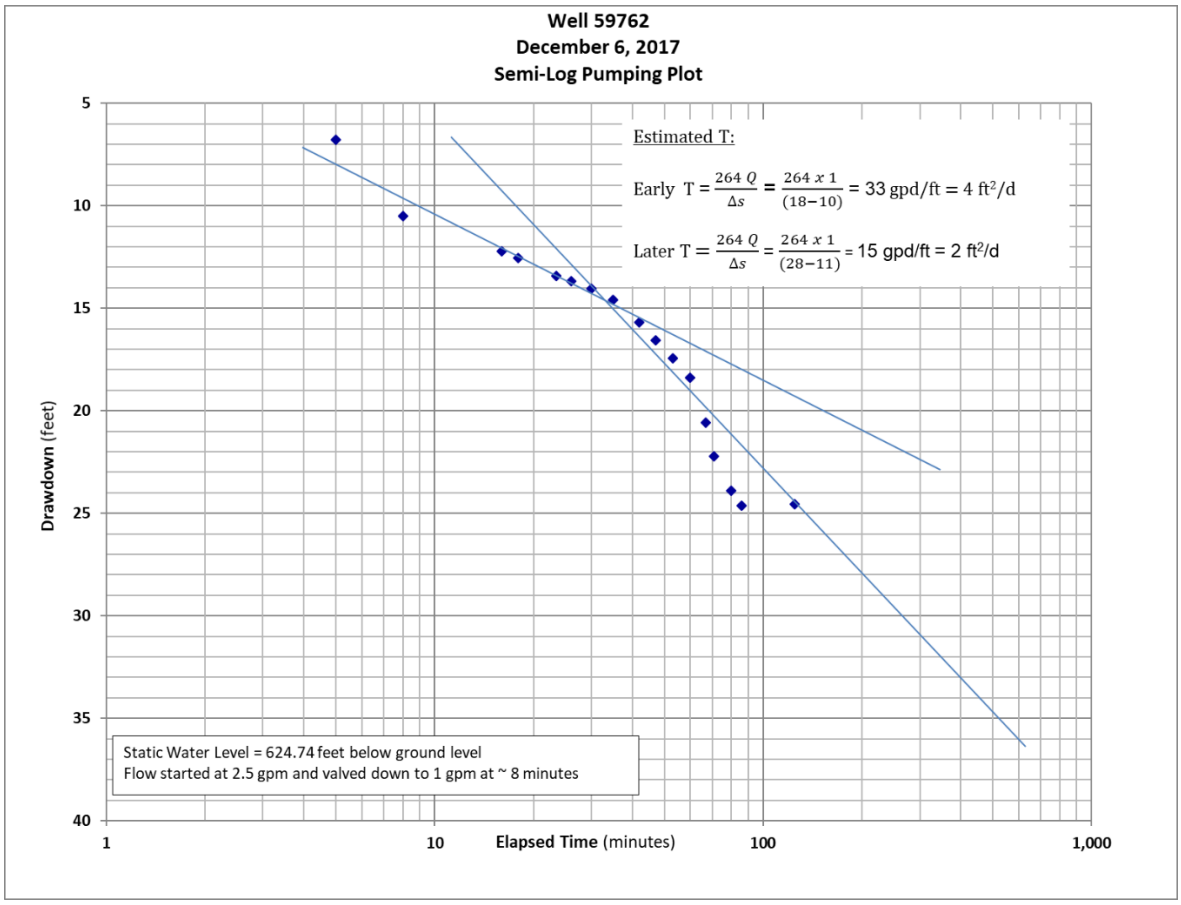

Figure 33. Well 59762 aquifer test pumping analysis

Recovery was monitored through December 28, 2017. Water level in the well recovered to static conditions within approximately one day. Analysis of the recovery data (Figure 34) suggests an early- to middle-time transmissivity on the order of approximately 30 gpd/ft (or 4 ft^2/d), consistent with the drawdown estimate. The effective transmissivity is likely less than 4 ft^2/d based on the apparent negative boundary noticeable in the drawdown and recovery data. The late-time recovery response suggests a transmissivity of approximately 5 gpd/ft (0.7 ft^2/d).

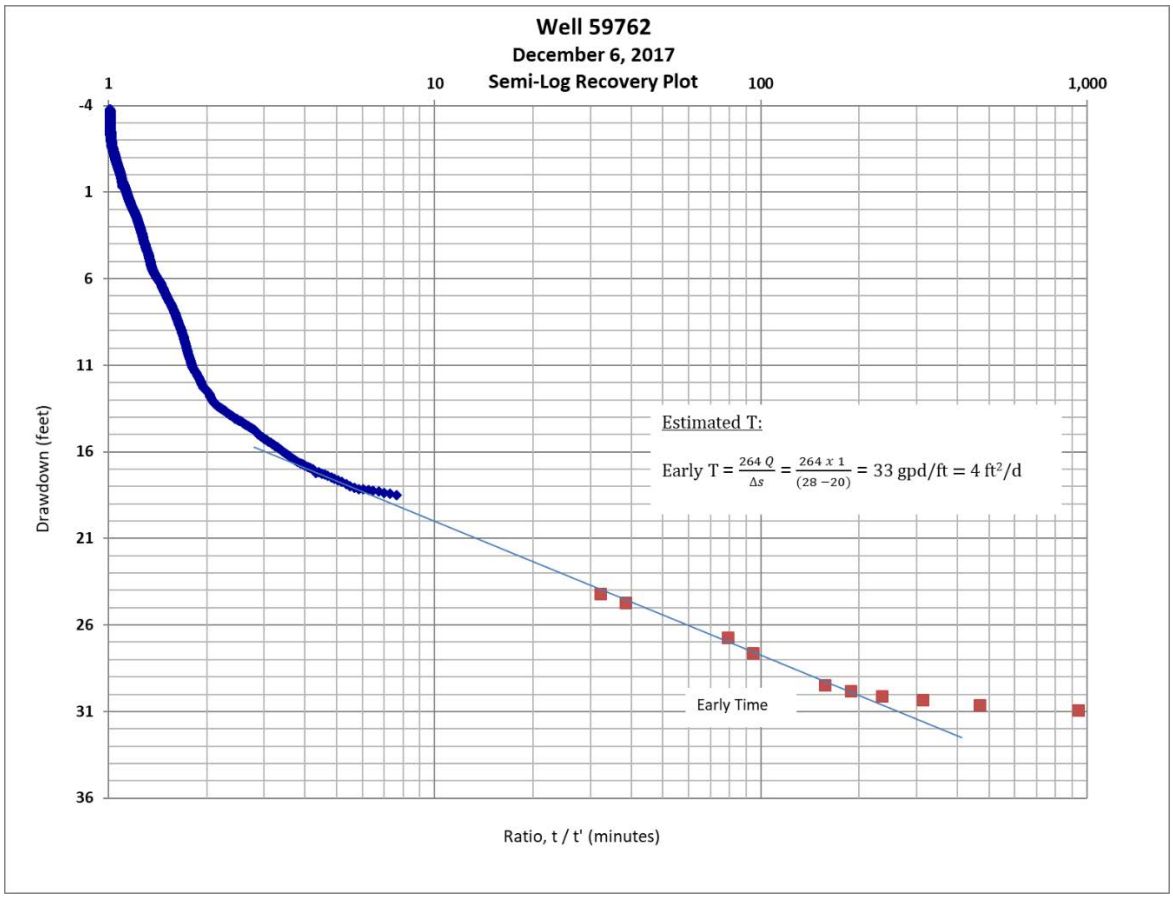

Figure 34. Well 59762 aquifer test recovery analysis

4.8.2.2 GMW17-32

Well GMW17-32 was installed in November 2017 to a depth of 718 feet bgs and screened from 678 feet to 718 feet bgs in alternating layers of tuff, arkose, siltstone, and clay. The lithology is moderately to highly silicified from a depth of 150 feet to 550 feet with trace or weak silicification above and below this zone. The borehole was initially advanced to 1,004 feet bgs but did not remain open for installing the well to this depth.

Well GWM-17-32 was tested on December 11, 2017. The static water level immediately before testing was 648.48 feet[9] bmp. The pump intake was set at approximately 717 feet bmp. The initial pumping rate of approximately 2.5 gpm was reduced to 1 gpm due to excessive drawdown in the well to near the pump intake.

A semi-log plot of the drawdown data is presented below as Figure 35. An aquifer transmissivity of approximately 5 gpd/ft (0.6 ft²/d) is estimated using the drawdown data and

[9] The water level in the well appeared to be recovering from previous short duration pumping events. Based on a longer period of recovery, the actual static water level may be closer to 635 feet bmp based on measurement on December 28, 2017.

a pumping rate of 0.9 gpm (water pumped from formation and not from casing storage). Assuming a saturated aquifer thickness of 200 feet would result in an estimated hydraulic conductivity of 0.003 ft/d. If only the screened interval contributed flow to the well with a saturated thickness of 40 feet, the assumed hydraulic conductivity would be 0.015 ft/d.

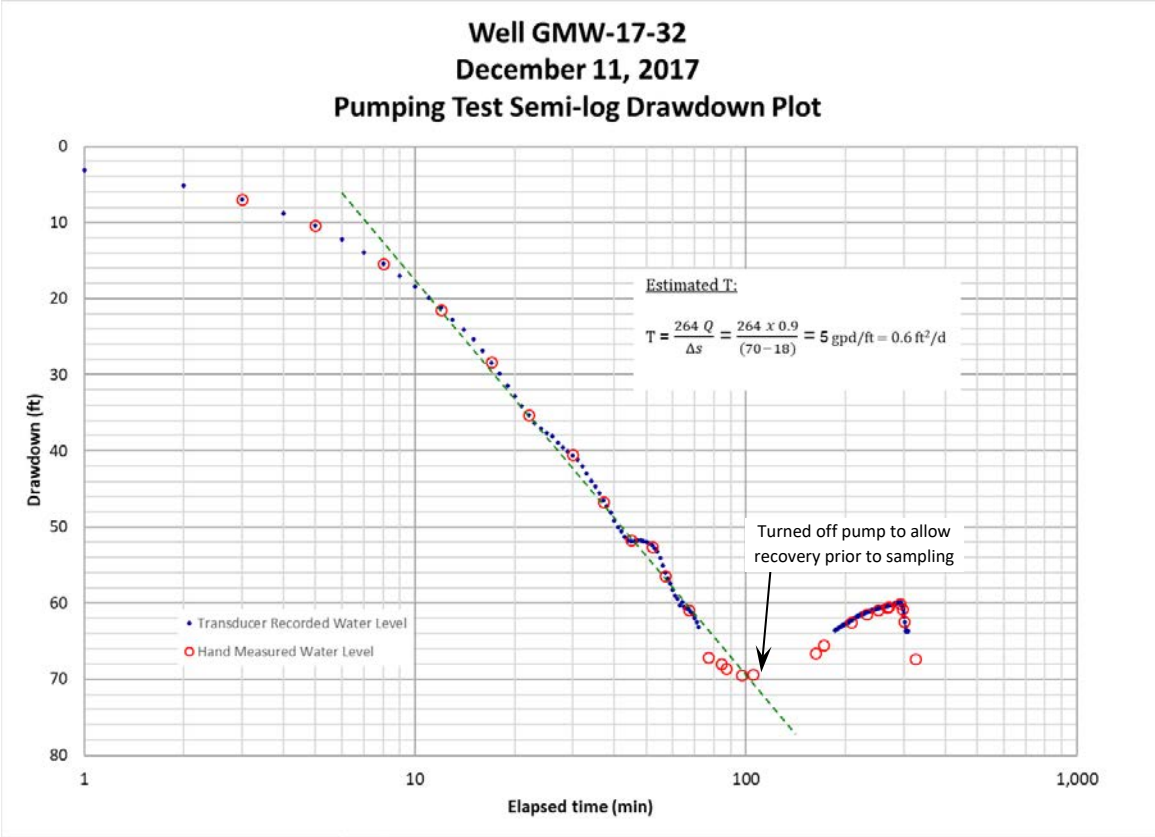

Figure 35. GMW17-32 pumping test semi-log drawdown plot

Figure 36 is a semi-log plot of the recovery data collected following the test pumping. An aquifer transmissivity of approximately 0.6 gpd/ft (0.08 ft^2/d) is estimated using the recovery data after approximately 200 minutes and an average pumping rate of 0.9 gpm. Assuming a saturated aquifer thickness of 200 feet would result in an estimated hydraulic conductivity of 0.0004 ft/d. Assuming a saturated thickness of 40 feet, the assumed hydraulic conductivity would be 0.002 ft/d.

Testing of this well suggests an aquifer transmissivity of between 0.6 to 5 gpd/ft and a hydraulic conductivity ranging from 0.002 to 0.015 ft/d (assuming only the screened interval is contributing flow to the well). The transmissivity and conductivity values are considered to be very low and are assumed to reflect the highly silicified nature of the aquifer materials.

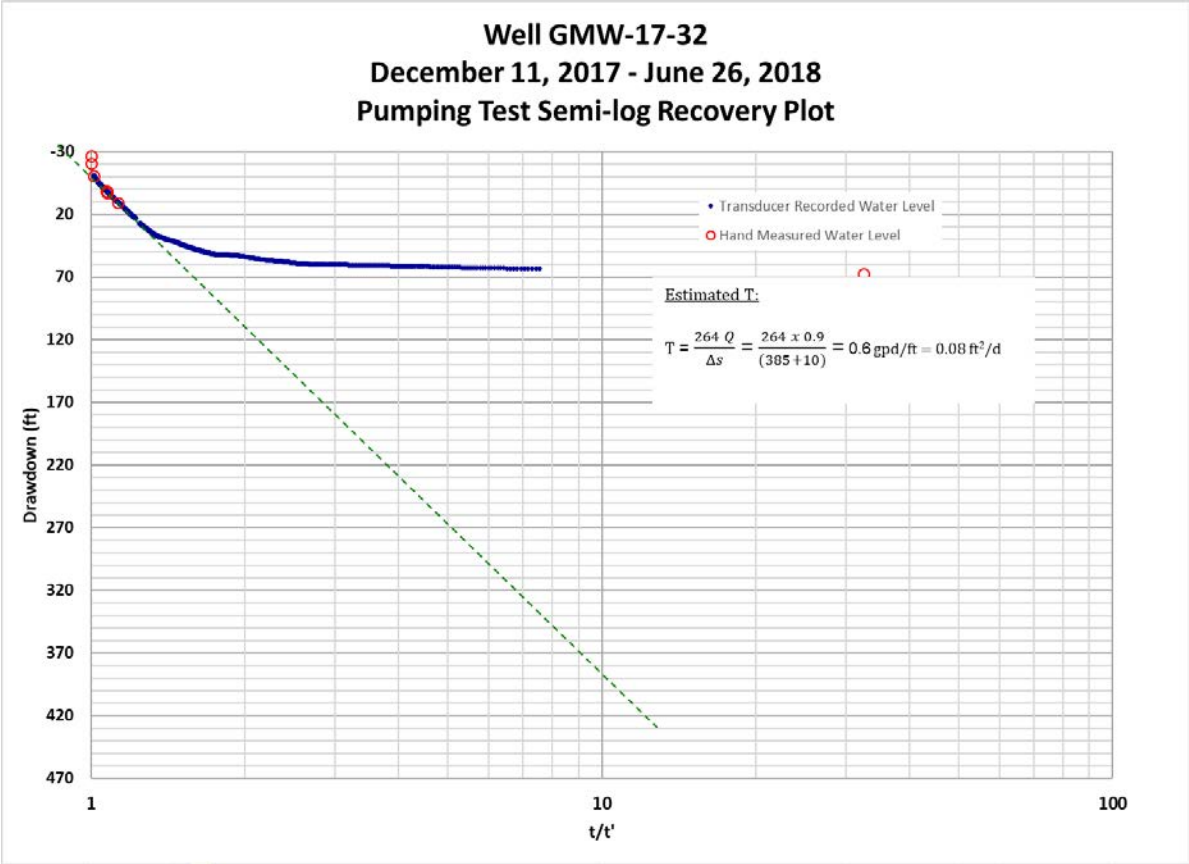

Figure 36. GMW17-32 pumping test semi-log recovery plot

4.8.2.3 GMW17-33

Well GMW17-33 was completed in November 2017 to a depth of 338 feet bgs, with screen placed from 238 feet to 338 feet bgs in alternating layers of sinter and silicified siltstone with traces of tuff and clay.

Well GMW17-33 was tested between December 14 and 18, 2017. The static water level was initially 244.13 feet bmp. The measurement point was approximately 1.06 feet above the 4-inch well casing. The pump intake was set at 338 feet bmp. The initial pumping rate was approximately 30 gpm. The rate was adjusted during periods throughout the pumping test in response to apparent negative boundary and increased drawdown effects. The final pumping rate was reduced to approximately 17.5 gpm, for an average pumping rate of 28 gpm over the pumping period. The total drawdown in the well at the end of the pumping period was approximately 46 feet.

The transmissivity obtained from a match to the early-time data (Figure 37) was approximately 620 gpd/ft (80 ft^2/d). Approximately 500 minutes into the pumping test, the drawdown appeared to stabilize for about 1 day, possibly attributed to delayed yield effects, followed by a negative boundary effect after approximately 3,200 minutes of pumping. The pumping rate was periodically decreased to prevent the drawdown from reaching the pump intake. The estimated hydraulic conductivity near the well is estimated to be approximately 0.4 ft/d (encountered within one day of pumping), assuming a saturated aquifer thickness of 200 feet. The hydraulic conductivity with distance from the well would be less based on increased and unsustainable drawdown effects.

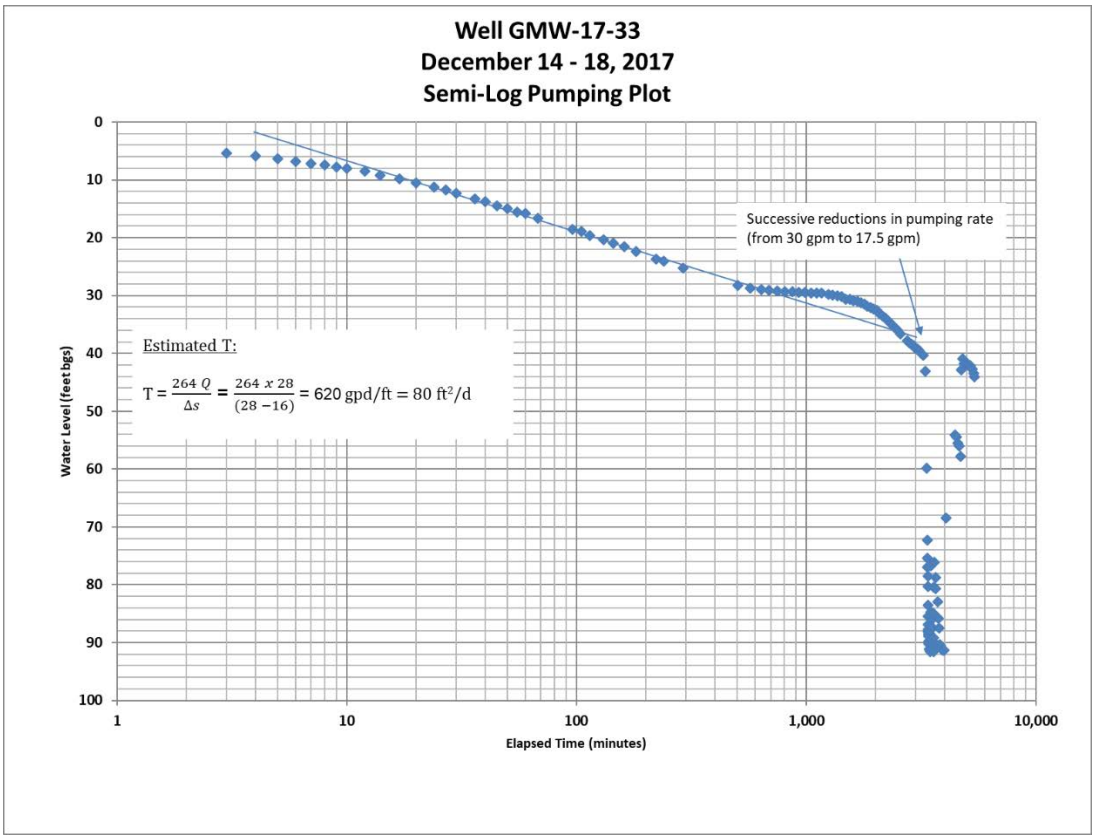

Figure 37. Well GMW17-33 aquifer test pumping analysis

Recovery monitoring was performed through December 28. An analysis of the recovery data (Figure 38) suggests an early-time transmissivity of 7,400 gpd/ft (1,000 ft^2/d) and a late-time transmissivity, reflecting the negative boundary condition, of approximately 280 gpd/ft (40 ft^2/d). The recovery data indicate an estimated hydraulic conductivity of 0.2 ft/d based on the late-time transmissivity and assuming a saturated aquifer thickness of 200 feet.

The non-linearity of the semi-log plot between early time and late time periods suggests the overall flow regime is not consistent with a two-dimensional (i.e., radial) flow regime. This response supports a dual porosity concept (i.e., compartmentalization of the aquifer, with higher versus lower permeability zones). This appears to be primarily related to silicification of the formation surrounding this well. Figure 18, showing GMW17-33 along with the CSAMT geophysical survey, indicates that the well is completed in less- or un-silicified material surrounded by more silicified formation. A cross section of this well with the CSAMT survey data (Line 10) is provided as Figure 20.

During testing of GMW17-33, the more permeable aquifer materials that the well targeted appear to have been dewatered, causing the observed decline in transmissivity. The much less permeable materials on the periphery of the target zone could not supply enough water to sustain the pumping rate and significant drawdown was observed. It is reasonable to

assume that any required dewatering of similar water-bearing zones in the proposed Grassy Mountain Mine would follow a similar pattern.

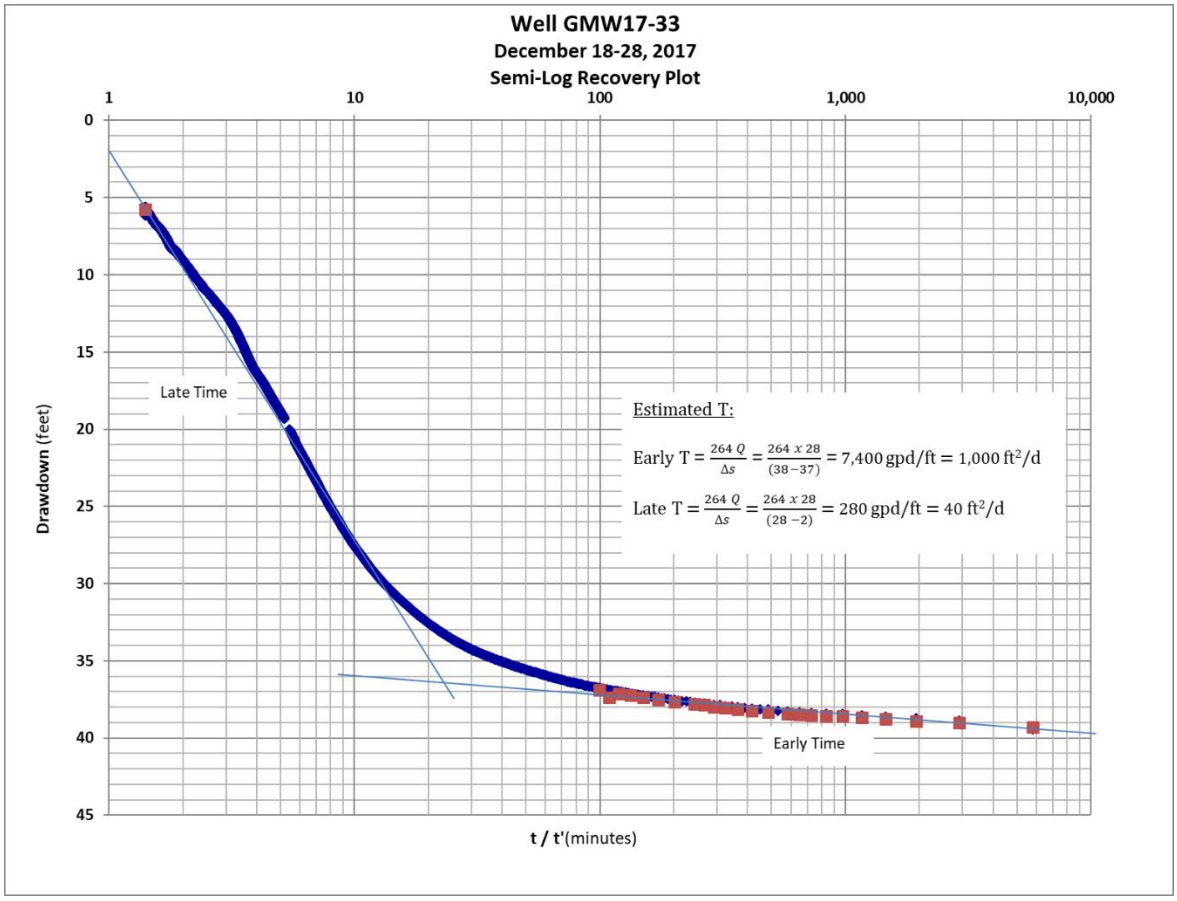

Figure 38. Well GMW17-33 aquifer test recovery analysis

4.8.2.4 Conclusions

Overall, the historic and recent aquifer testing (i.e., PW-1, PW-4, Prod-1, GMW17-33) indicates that portions of the regional aquifer with higher transmissivity occur locally in proximity to the wells and that, as testing progresses over time, lower transmissivity regions are encountered based on negative boundary effects. These results suggest the conductive portions of the aquifer system are either compartmentalized or limited, with flow provided to wells initially via permeable zones (i.e., sand, sandstone, fractured basalt, etc.) that are limited in spatial extent. With longer pumping, the radius of influence from testing expands and intercepts predominantly lower permeability deposits (i.e., arkosic sandstone, silicified sediments, competent bedrock, faults as hydraulic barriers, etc.).

Hydraulic conductivity in the of the proposed Grassy Mountain Mine increases moving north away from the deposit area, likely due to aquifer decreasing influence of silicification.

Testing of the most northern well, PW-4, suggests a hydraulic conductivity of approximately 3 ft/d. PW-4 is completed in un-silicified sandstone and conglomerate. The deep wells 59762 and GMW17-32 exhibit low transmissivity and hydraulic conductivity assumed to be representative of the silicified sediments at or near the deposit area, with hydraulic conductivities ranging from 0.0004 ft/d (GMW17-32) to 0.02 ft/d (59762). Results of packer testing at drill hole GM19-37 (discussed below) located within the mine deposit fell within this range, with a conductivity value of 0.004 ft/day. Estimates of hydraulic conductivity are sensitive to the assumed saturated aquifer thickness, with lower values obtained for thicker saturated aquifer extents. For the deep wells, the aquifer thickness is difficult to estimate as there is no information from drilling or lithology to develop an estimate. Based on previous investigations, aquifer thickness typically has been assumed to be on the order of 200 feet to 300 feet.

Drilling, test pumping, water level monitoring, and geophysical data all indicate that average hydraulic conductivities and corresponding aquifer transmissivities in the vicinity of the deposit area are very low. As a result, groundwater inflows to proposed mine workings should also be low.

4.8.3 Packer Testing Drill Hole GW19-37 and Secondary Porosity from Fracture Flow

Limited data on aquifer properties were available within the mine deposit prior to the packer test performed by Lorax Environmental on GW19-37 in October of 2019. The elevation at the surface of GM19-37 is 3922 ft msl and the packer test was performed between 404 and 433 ft bgs. Drill hole inclination is 70° which puts the elevation of the packer test between the approximate elevations of 3529 and 3515 feet msl. Hydraulic conductivity was calculated using Hvorslev, 1951. An estimated value of 0.004 ft/day or a transmissivity of 0.8 ft^2/day was determined assuming a saturated thickness of 200 feet (Lorax 2020).

With the limited hydraulic data available in the deposit area, the geotechnical core logging data for GM19-37 was compared to other drill holes to determine the likelihood of similar hydraulic conductivity values. Geotechnical data are included in Golder Associates (2018) and GMS (2020). Characteristics such as fracture frequency, joint conditions, rock quality designation, and rock strength were evaluated by Golder Associates to determine a rock mass rating (RMR). Based on all of these characteristics, RMR is divided into a ranking system with five categories:

1. Very Good
2. Good
3. Fair
4. Poor
5. Very Poor

The RMR of 27 drill holes were evaluated and the cumulative RMR for drill holes indicated that a majority of core was categorized as “Fair” (49%) or “Poor” (38%). The remaining 13% were identified as either “Very Good”, “Good”, or “Very Poor”. The entire length of core for

GM19-37 was consistent with other boreholes with 45% “Fair” and 37% “Poor”. The packer test at GM19-37 was performed between 404 and 433 feet and this section of core is described as both Fair and Poor. Therefore, it is assumed that the hydraulic conductivity determined by the packer test is reasonably representative of the mine area as a whole. Given the high degree of silicification around the deposit area, groundwater flow in this area is mostly likely by way of flow through joints and fractures in the rocks The locations of GM19-37 and the 26 other drill holes are presented in Figure 39.

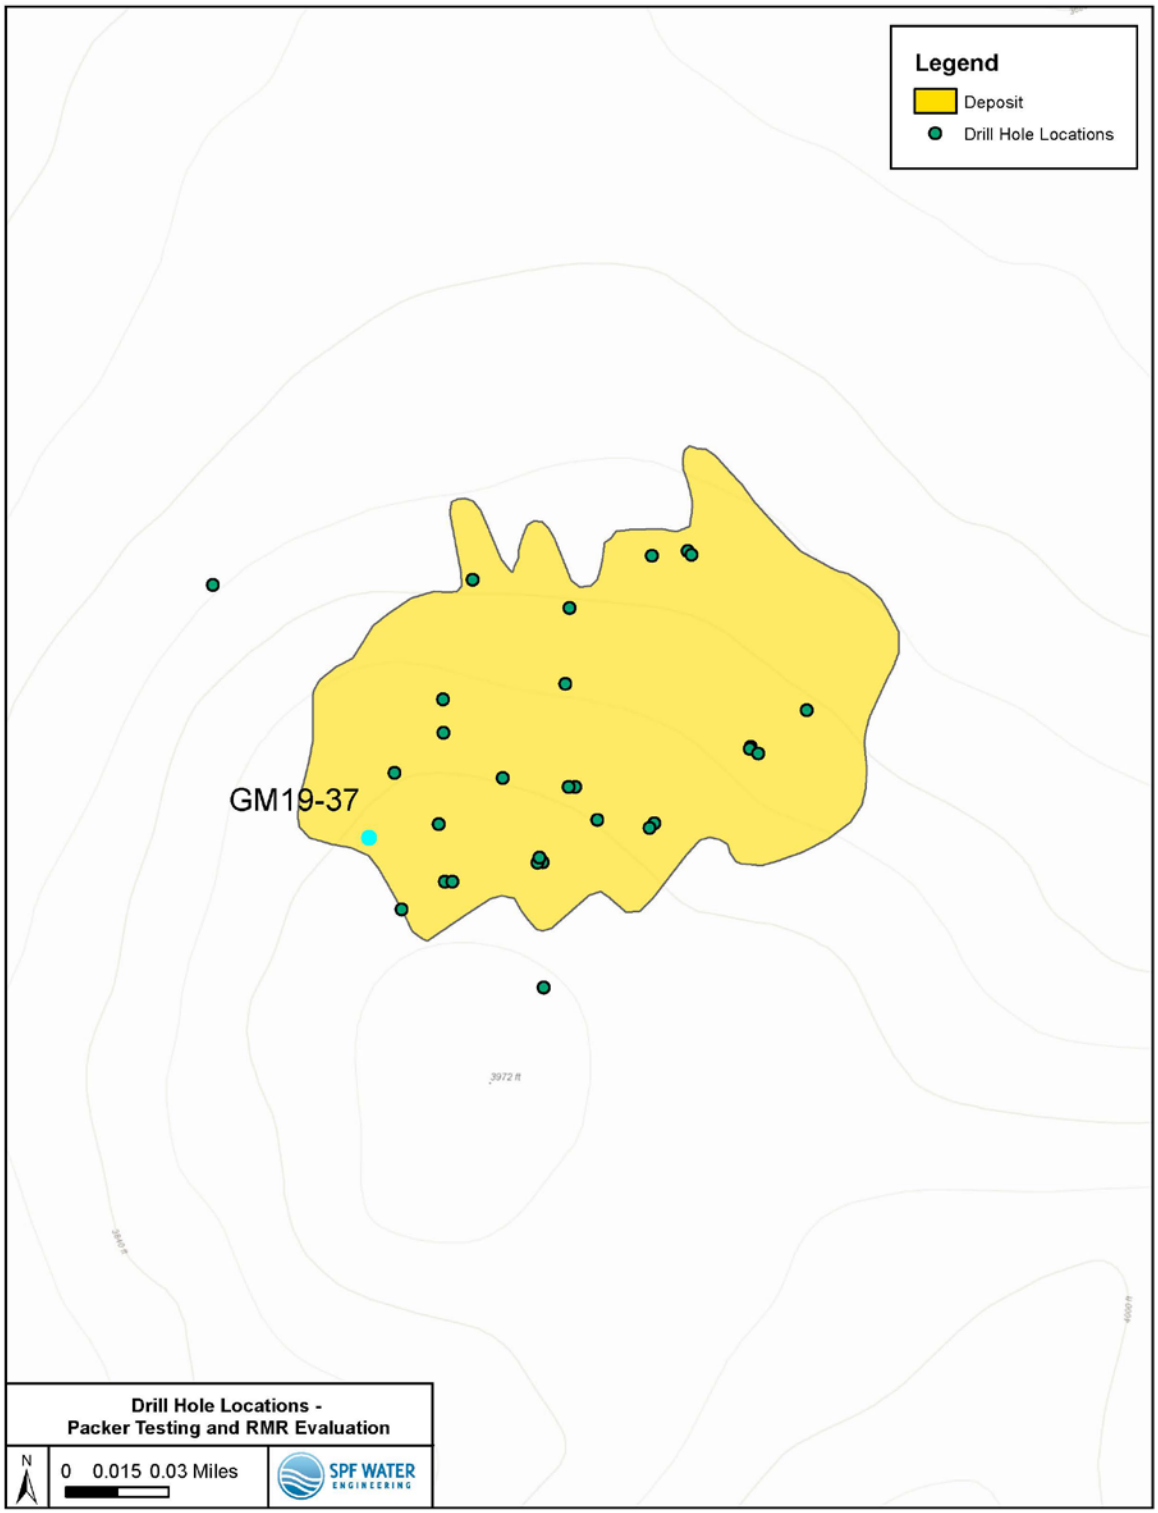

Figure 39. Drill Hole Locations for Packer Testing and RMR Evaluation

4.9 Water Balance

A water balance is determined from the amount of groundwater recharge derived from infiltration during precipitation events and inflow from surface water and groundwater minus the amount of evapotranspiration and outflow from surface water and groundwater, accounting for any changes in storage (Fetter, 1980). Available information to date on the water balance for the Grassy Mountain vicinity is largely based on previous investigations. The basis for the water balance has been derived from hydrogeologic conceptual models for similar basins located in other, semi-arid regions in the western US and from previous numerical modeling efforts performed for Grassy Mountain (ABC, 1992).

4.9.1 Recharge

Annual recharge to groundwater in the vicinity of Grassy Mountain was estimated by others to be in the range of 0.25 to 1 inch based on climatic and topographic conditions (ABC, 1992). Assumptions made regarding the potential range of recharge is discussed further in section 3.2 of the *Dewatering Projections and Evaluation of Potential Pumping Impacts, Grassy Mountain Gold Project* (SPF, 2021b). These values were supported by ABC's numerical groundwater flow model of Grassy Mountain, with an assigned recharge rate of 0.5 inches per year (ABC, 1992). The total annual precipitation for the area is approximately 10 inches, mostly as snow during winter, with higher precipitation amounts between November and May (around one inch each month) compared to hotter, drier summer months and shoulder seasons between June and October, typically a few tenths of an inch as shown in Table 8 below (WRCC, 2017).

OWYHEE DAM, OREGON													
NCDC 1981-2010 Monthly Normals	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec	Annual
Mean Precipitation (in.)	0.92	0.76	0.89	0.96	1.16	0.92	0.43	0.38	0.45	0.64	0.92	1.25	9.68

Table 8 . Owyhee Dam Mean Precipitation

Data was also obtained from the Kelsey Butte weather station to help confirm this amount of precipitation for more recent years and at higher elevation than the Owyhee Dam as show in Figure40 below (Meso West 2019).

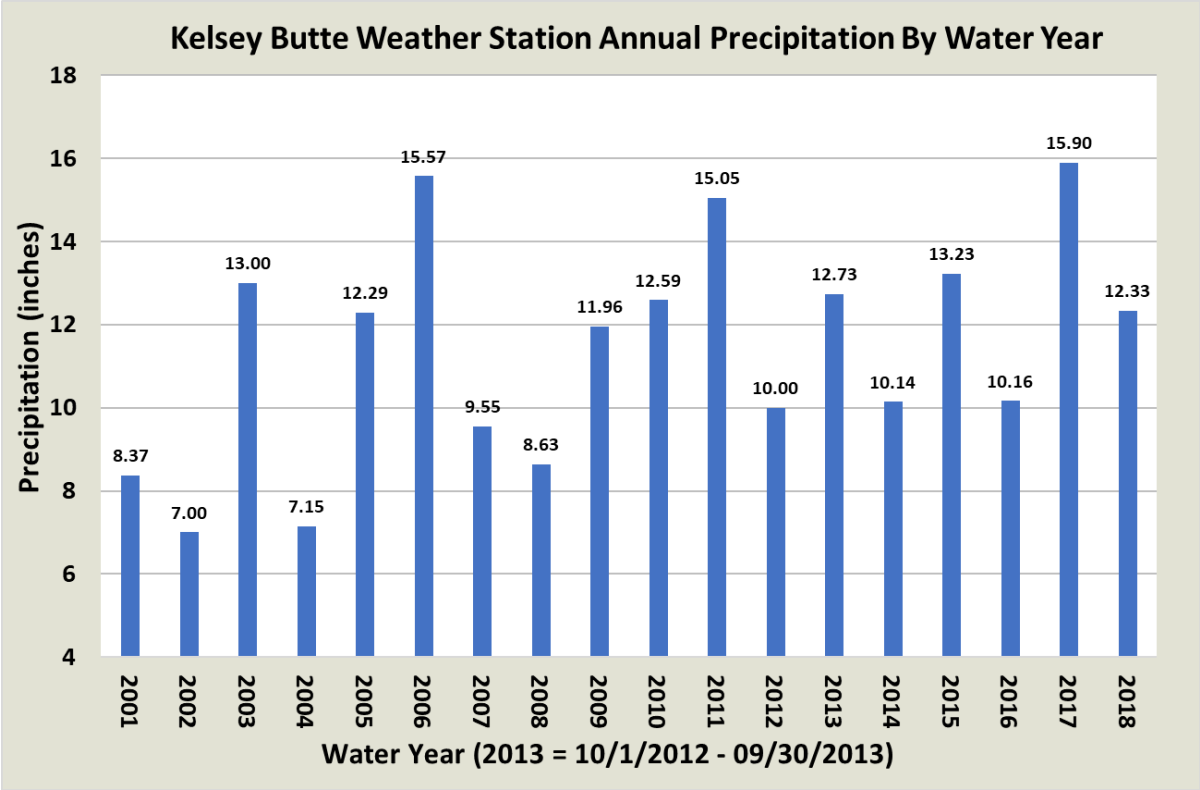

Figure40. Kelsey Butte Weather Station Annual Precipitation

Figure A2 in Appendix A shows surficial geology (Ferns 1993) along with the surface water hydrologic unit borders. Southeast of the proposed Grassy Mountain Mine, Grassy Mountain serves as the hydrologic divide between Negro Rock Canyon and the Owyhee River. It is assumed that this divide generally applies to both surface water and groundwater. The Negro Rock Canyon drainage flows into Sand Hollow and ultimately into the Malheur River near Vale, Oregon.

While topography identifies Grassy Mountain as the hydrologic divide, surficial geology also suggests that the groundwater divide is near Grassy Mountain. The contact between the Grassy Mountain Formation (unit *Tsau*) and the underlying Tuff of Kern Basin (unit *Ttkb*) surfaces on Grassy Mountain just to the south of the topographic divide. The Grassy Mountain Formation dips towards the north, in the direction of Negro Rock Canyon. The aquifer system in the vicinity of the proposed Grassy Mountain Mine occurs within the Grassy Mountain Formation, so any precipitation that falls on the contact or downgradient would be expected to recharge the aquifer. Figure A2 shows that the recharge area for the proposed Grassy Mountain Mine is relatively small, on the scale of 1 to 3 square miles.

4.9.2 Discharge

Grassy Mountain serves as the groundwater divide between Negro Rock Canyon and the Owyhee River, supported by topography and geology. Ultimately Negro Rock Canyon

discharges to the north to the Malheur River. While the Owyhee Reservoir and Owyhee River are the predominant regional drainage features near the proposed Grassy Mountain Mine, regional groundwater flow is to the north towards the Malheur River.

Locally, ephemeral reservoirs (including Schweizer Reservoir, Grassy Mountain Reservoir, and Grassy Reservoir) and ephemeral streams provide surface water discharge for the area (JMM, 1991).

Springs are local discharge features for groundwater that may result from the contact between lithologic units with different permeabilities or may be associated with faults, joints, or fractures (Fetter, 1980). Within the Grassy Mountain vicinity, numerous individual springs (some ephemeral) have been identified and have been monitored for flow and water quality during investigations for baseline and background characterization purposes. The majority of springs have measured flow rates of less than one gpm, although the flow rate in several springs have been measured over 1 gpm. The discharge from monitored springs located on the north side of the Grassy Mountain hydrologic divide is on the order of approximately 30 gpm based on flow measurements collected between 2013 and 2017. There are additional springs farther downgradient that were not monitored for flow that could also serve as regional groundwater discharge points. The total aggregate visible groundwater discharge is an indicator of the low annual recharge rate.

5 WATER QUALITY

5.1 Baseline Groundwater Quality Monitoring

5.1.1 Monitoring Wells

Quarterly groundwater quality data were collected from 12 monitoring wells between the 1st Quarter of 2013 and the 3rd Quarter of 2014. The new monitoring wells GMW17-32 and GMW17-33, plus the pre-existing well 59762, were sampled once[10] for water quality in accordance with the Final Work Plan for Grassy Mountain Monitoring Wells (SPF, 2016b).

A list of wells, locations, construction details, sampling protocols, water quality data, and QA/QC results are presented in the groundwater baseline report (SPF, 2019). The baseline sampling of the wells indicate that the area groundwater does exceed primary and secondary maximum contaminant levels (MCLs) for drinking water. These analytes include arsenic, antimony, and lead for the primary standards and aluminum, iron, manganese, total dissolved solids (TDS), and sulfate for the secondary standards.

[10] GMW17-32 was actually sampled for water quality three times, but only the third and final results are considered baseline data and occurred after significant re-development of the well.

Arsenic is the most common analyte to exceed a primary MCL. All fifteen (15) of the wells sampled produced groundwater that exceeded the MCL of 0.010 mg/L. The wells and the range in total arsenic values are listed below:

- 59760 (between 0.0245 – 0.0283 mg/L).
- 59761 (between 0.0219 – 0.0244 mg/L).
- 59762 (between 0.163 mg/L) on December 16, 2017.
- 59763 (between 0.0600 – 0.0787 mg/L).
- 59766 (between 0.01847 – 0.0276 mg/L).
- 59772 (between 0.0348 – 0.038 mg/L).
- Bishop (0.0101 mg/L, total only) on September 15, 2014.
- BLM (between 1.54 – 4.63 mg/L).
- GMW17-32 (0.0799 mg/L) on December 5, 2018.
- GMW17-33 (0.107 mg/L) on December 14, 2017.
- GW-1 (between 0.0268 – 0.0313 mg/L).
- GW4 (between 0.0111 – 0.0126 mg/L).
- Prod-1 (between 0.0579 – 0.0615 mg/L).
- PW-1 (between 0.0282 – 0.0331 mg/L).
- PW-4 (between 0.0148 – 0.0221 mg/L).

Total arsenic concentrations more than three times the 0.010 mg/L MCL are common in groundwater within the basin (Figure 41). This figure represents the most recent measured arsenic concentration in each well. The presence of naturally-occurring arsenic in groundwater at concentrations above the MCL have an association with some felsic volcanic rocks and mineralized areas (Welch, et. al., 2000). The ore body at Grassy Mountain would constitute a mineralized zone.

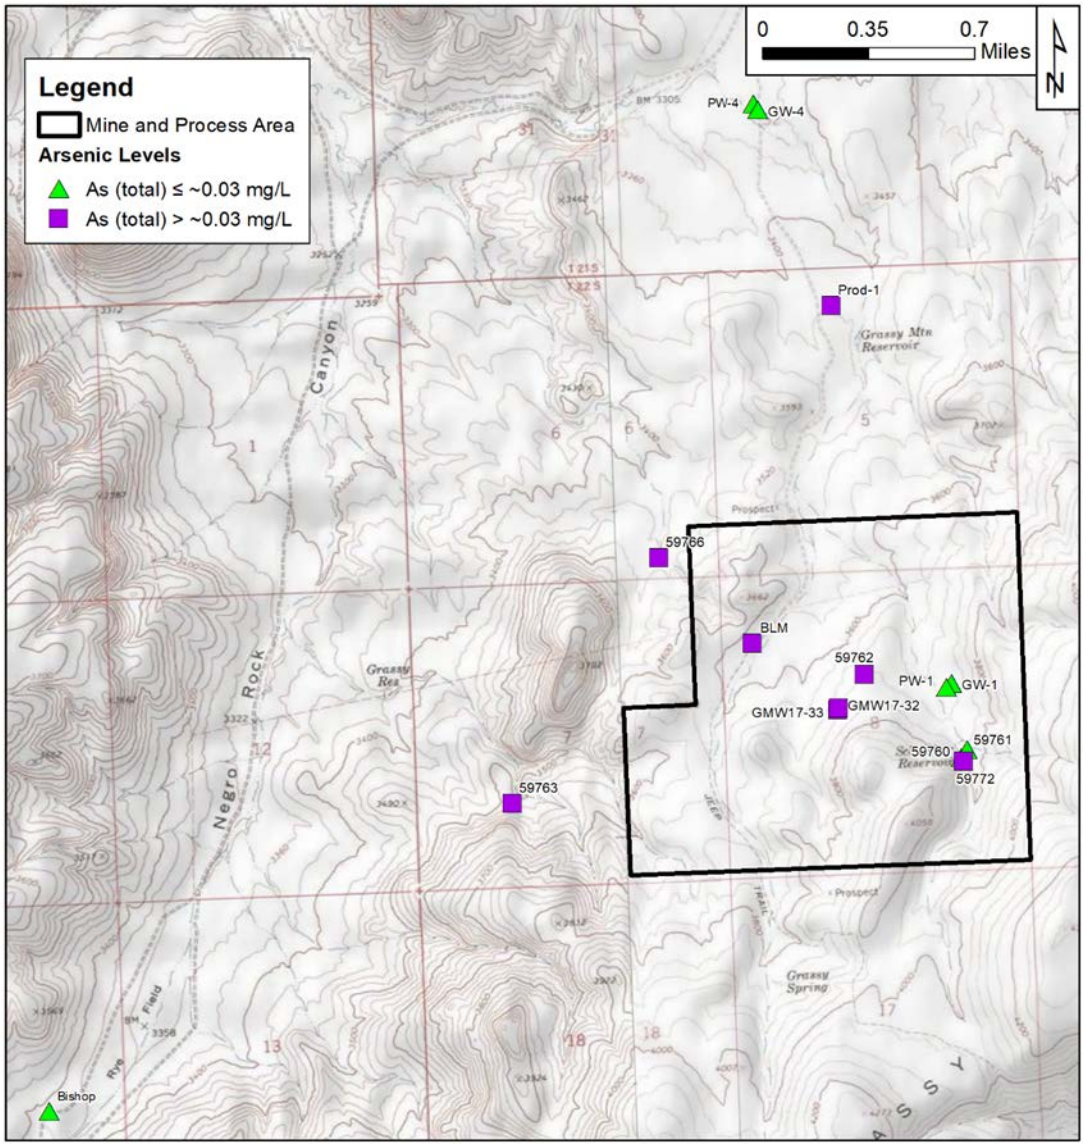

Figure 41. Total arsenic concentration distribution in groundwater

Antimony was detected at above the drinking water MCL of 0.006 mg/L at the following well locations:

- 59762 (0.21 mg/L total and 0.298 mg/L dissolved) on December 12, 2017.
- GMW17-32 (0.0374 mg/L total and 0.0371 mg/L dissolved) on December 15, 2018.
- GMW17-33 (0.0244 mg/L total and 0.0217 mg/L dissolved) on December 14, 2017.

These wells are located just downgradient of the deposit area. Antimony has been detected in other wells at concentrations below the MCL (less than 0.002 mg/L)

Chromium was initially detected above the MCL (0.1 mg/L) in GMW17-32, but after redevelopment was below the MCL. Chromium was also detected (below the MCL) at other sampled locations within the Grassy Mountain vicinity, including 59760, 59761, 59763, 59766, 59772, GW-4, PW-1, and PW-4 at concentrations ranging from 0.0005 mg/L to 0.0017 mg/L, suggesting the presence of a naturally occurring source for chromium at low concentrations.

Lead was detected above the MCL (0.015 mg/L) on the initial sampling events of GMW17-32 and 59766. On subsequent sampling events, the lead concentration remained under the MCL.

5.1.2 Springs

Quarterly water quality data were collected from up to 11 baseline springs between the 1st Quarter of 2013 and the 3rd Quarter of 2014. A list of springs, locations, sampling protocols, water quality data, and QA/QC results are presented in the groundwater baseline report (SPF, 2019). The baseline spring sampling indicate that the area groundwater does exceed primary and secondary maximum contaminant levels (MCLs) for drinking water. These analytes include arsenic for the primary standards and aluminum, manganese, and TDS for the secondary standards.

Arsenic was the only constituent with reported concentrations above a primary MCL at sampled spring locations. Arsenic was detected above the MCL at seven of the ten sampled spring locations:

- Deposit Stock Tank (0.025 – 0.031 mg/L),
- Poison Spring (0.033 – 0.040 mg/L),
- Sourdough Spring Lower (0.023 – 0.026 mg/L),
- Sourdough Spring Upper (0.027 – 0.032 mg/L),
- Twin Springs North (0.042 – 0.061 mg/L)
- Twin Springs South (0.040 – 0.049 mg/L), and
- Whiskey Spring (0.082 – 0.100 mg/L).

The range in arsenic concentrations was relatively consistent at all detected locations (i.e., on the order of approximately 0.020 to 0.030 mg/L). The highest detections were reported at Whiskey Spring (on the order of approximately 0.080 to 0.100 mg/L). Arsenic was not detected above the MCL at Government Corral Spring, Sagebrush Spring, or Lowe Spring.

5.2 Geochemical Characteristics

Geochemical characteristics of the groundwater (wells and springs) were evaluated using Trilinear diagrams and Stiff diagrams, with major ions expressed as meq/L. These diagrams are useful for evaluating the geochemical signature of the water, to illustrate general differences in water chemistry using major ions, and to group waters with similar chemical signature into identifiable groups (or hydrochemical facies). Geochemistry results from all of the sampled springs and wells are presented in the groundwater baseline report (SPF, 2019).

5.2.1 Well Geochemical Characteristics

The predominant hydrogeochemical facies noted for groundwater sampled from wells within the Grassy Mountain project vicinity include:

- Calcium bicarbonate (Ca-HCO3) for 59760, 59761, 59722, and GW-1.
- Sodium-potassium bicarbonate (Na/K-HCO3) Bishop, GW-4, Prod-1, and PW-1.
- Sodium-potassium sulfate (Na/K-SO4) for 59763, 59766, BLM, 59762, and GMW17-32.

A fourth water quality type (calcium-sulfate, Ca-SO4) was previously described for wells GW-3 and GW-5 based on historical sampling events (JMM, 1991). A calcium-sulfate water type has not been observed elsewhere based on subsequent sampling events.

A map of each of the wells and its associated geochemical signature is included as Figure D-1 in Appendix D. The predominant water types appear to have a spatial distribution attributed to local geologic conditions and areas of recharge/discharge. Predominantly Ca-HCO3 water types are noted in wells to the east of deposit area that are generally completed in basalt. Groundwater sampled from wells located directly downgradient of the deposit area and near silicified sections of the aquifer appear to exhibit Na/K-SO4 water types. The rest of the wells located in the Grassy Mountain Formation downgradient of the deposit area and away from silicified zones exhibit Na/K-HCO3 water types. The presence of calcium may be attributed to areas with basalt deposits, and sodium may be associated with volcanic tuff and sedimentary deposits. Sulfate may be associated with areas immediately downgradient of the ore body and potentially attributed to longer residence times due to lower hydraulic conductivity and/or oxidation and leaching of the ore deposit (ABC, 1992).

In addition to wells downgradient of or within the ore body being a Na/K-SO4 facies (BLM, 59766, GMW17-32, GMW17-33, 59763, and 59762), these wells all had elevated values of arsenic, iron, manganese, boron, molybdenum, and nickel (Figure 42) relative to other baseline monitoring locations. These constituents are known to leach from ore and waste rock from the deposit, based on geochemical analyses (SRK, 2021). The pH at the BLM well and to a lesser degree at 59766 is also slightly depressed relative to other monitoring locations (6 to 7.9 versus typically >8). The unique geochemical signature at these wells (the particular suite of elevated constituent concentrations and sometimes depressed pH) indicates an influence on water quality down-gradient from the deposit minerals, influencing baseline water quality conditions in and down-gradient of the ore deposit.

*Detections below reporting limit averaged using reporting limit value.

Figure 42. Average Metal Concentration 2013-2018

Wells PW-1 and GW-1, despite being fairly close together, exhibit different geochemical signatures. GW-1 is screened in shallow gravel deposits and exhibits a Na/K-HCO3 water type like the wells farther downgradient of the deposit area. PW-1 is screened deeper in unconsolidated clay and sand and sandstone. PW-1 produces groundwater with a Ca-HCO3 signature, like the up-gradient wells completed in basalt.

Deeper wells (59762 and GWM17-32) suggest a predominant Na/K-SO4 water type that is also apparent at shallow well locations (i.e., BLM, 59763, and 59766) hydraulically downgradient of the deposit area. This suggests downward migration of groundwater within the silicified zone.

5.2.2 Spring Geochemical Charactersitics

Three predominant hydrogeochemical facies are apparent based on sampling events performed during 2013 and 2014 at spring locations:

- Sodium-potassium bicarbonate (Na/K-HCO3) for Poison Spring, Sourdough Springs (lower and upper), Twin Springs (North and South), and Lowe Spring.
- Calcium bicarbonate (Ca-HCO3) for Government Corral Spring, Sagebrush Spring, and Deposit Stock Tank.
- Sodium-potassium sulfate (Na/K-SO4) for Whiskey Spring.

A map of each of the springs and its associated geochemical signature is included as Figure D-2 in Appendix E. An apparent spatial distribution is noted at certain spring locations. For example, springs with a dominant water type Ca-HCO3 (including Government Corral Spring, Sagebrush Spring, and Deposit Stock Tank) are located primarily north and northeast of the proposed Grassy Mountain Mine. Like the wells that have a Ca-HCO3 signature, Government Corral Spring, Sagebrush Spring, and Deposit Stock Tank are located near volcanic formations. A Na/K-HCO3 water type is the most prevalent signature from springs in the area and appears to be representative of the main regional flow system. A Na/K-SO4 water type is apparent at Whiskey Spring.

Whiskey Spring is located approximately 4 miles southeast of the proposed Grassy Mountain Mine on the south side of Grassy Mountain. However, the Whiskey Spring arsenic concentrations were on the order of two times higher than the concentrations observed at any other spring. Whiskey Spring appears to be flowing out of the *Tas* geologic formation, the arkosic and tuffaceous sandstone underlying the Kern Basin Tuff formation. The elevation of this spring is approximately 3,225 feet amsl, which is higher in elevation than some of the deeper well water levels located near the mine. The water for this spring may have flowed through a separate mineralized zone in the area.

5.2.3 Interpretation of Groundwater Geochemical Characteristics

Figure D-3 in Appendix D maps the geochemical signature of both the wells and the springs. This figure suggests that the aquifer to the east and northeast of the deposit area generally has a Ca-HCO3 signature, likely associated with volcanics. The aquifer immediately downgradient of the deposit area is predominantly a Na/K-SO4 water type. The presence of

sulfate could be related to very low permeability near the deposit area and/or oxidation and leaching of sulfide minerals in the ore deposit (ABC, 1992).

Whiskey Spring exhibits geochemistry similar to the groundwater immediately downgradient of the deposit area, although several trace constituents observed in the wells downgradient of the mine are not elevated in the Whiskey Spring water (the exception being arsenic). This spring appears to originate where the Kern Basin Tuff surfaces. Even though this spring is at a higher elevation than the presumed water surface within the deposit area and in a different hydrologic basin, the groundwater appears to be influenced by the same type of silicification associated with the deposit area.

The groundwater located in the main regional flow system downgradient of the deposit area exhibits a Na/K-HCO3 chemistry. Sodium may be associated with volcanic tuff and sedimentary deposits.

Figure D-3 supports the idea of a single aquifer system, with chemistry influenced by lithology. Wells immediately downgradient of the deposit area exhibit the same geochemical signature and elevated leached metals and appear to be affected by the deposit characteristics, regardless of well depth. Groundwater farther from the proposed Grassy Mountain Mine also exhibits its own signature influenced by lithology, regardless of well depth.

Figure D-4 in Appendix E displays the trilinear diagrams of both the wells and springs for comparison purposes. It is apparent that as the groundwater moves away from the volcanic formations it tends to decrease in calcium concentration. The same is true with sulfate and the silicified areas of the Grassy Mountain Formation. The groundwater upgradient (or not in the downgradient path) of the groundwater flowing through silicified and mineralized sediments (Bishop, 59761, 59760, 59772, PW-1, and GW-1) has the least amount of sulfate. The groundwater downgradient of the silicified sediments (Prod-1, GQ-4, PW-4, GMW17-33) shows an increase in sulfate. Even though GMW17-33 is located near the deposit area, it is completed in the middle of what appears to be a section of unsilicified material (Figure 20). The wells located in silicified media appear to have the highest concentrations of sulfate and relatively the least desirable water quality from a drinking water standpoint. The trend of the cations presented on these trilinear diagrams indicates ground water movement throughout the aquifer system.

Looking at Figure D-4, it appears Well GW-4 and Poison Spring have a similar geochemical signature. Even though Lowe Spring, Government Corral, and Deposit Stock Tank are closer to GW-4, Poison Spring pairs better with the geochemical signature of GW-4. This suggests that Poison Spring could be connected to the deeper section of the aquifer while the other springs are discharge points for shallower less confined or perched sections of the aquifer.

6 GROUNDWATER CONCEPTUAL MODEL

The aquifer system in the vicinity of the Project occurs within the Grassy Mountain Formation, generally consisting of arkosic sandstone, siltstone, and conglomerate. The unit includes

interbedded fine-grained sediments. The Grassy Mountain Formation is the host unit for the proposed Grassy Mountain Mine. The unit is underlain by the Kern Basin Tuff, a fine-grained lithic tuff.

Groundwater is typically found within the Grassy Mountain Formation in unconsolidated or weakly consolidated sandstone and conglomerate units and interbedded sediments. The water-bearing zones appear to be somewhat compartmentalized due to faults, sedimentary facies changes, and silicification in and around the deposit area. Cross-sections developed from available subsurface lithology demonstrate the variability in water-bearing strata throughout the Project area.

Water levels in the area are typically stable, with some seasonal variations evident in shallow wells or wells otherwise subject to more direct recharge. There is some evidence of a general long term water level decline in the shallow aquifer zone at several wells in the vicinity of the proposed Grassy Mountain Mine, possibly due to inadequately sealed boreholes at or near the proposed Grassy Mountain Mine allowing shallow aquifer zones to drain to deeper zones. The observed decline is on the scale of a few feet over several years.

The Grassy Mountain Formation in and near the deposit area is silicified and strongly indurated. Geophysical data indicates that the zone of silicification increases to at least an approximate depth of 1,300 feet below ground surface (Figure 14). Based on available information, a saturated zone occurs within the deposit area at an elevation ranging from 3,300 to 3,100 feet, which is above the expected maximum depth of the proposed mine (approximately 3,050 feet). However, this zone does not appear to be consistent throughout the deposit area. Anecdotal evidence from exploratory drilling suggests the presence of isolated perched water-bearing zones above an elevation of 3,300 feet. These zones may be associated with less-silicified material with higher conductivity, and faults in these areas may act as conduits for groundwater flow.

While portions of the proposed Grassy Mountain Mine are understood to be saturated, hydraulic conductivity and resultant groundwater flow appear to be severely restricted by silicification and/or faulting. Testing of GMW17-32 completed in silicified sediments near the deposit area suggests a very low hydraulic conductivity on the order of 10^{-6} to 10^{-7} cm/s. A long recovery period after testing this well also is an indication of very low hydraulic conductivity. Given the location of the proposed Grassy Mountain Mine relative to the groundwater divide, the available groundwater recharge to the area appears to be limited as well.

The silicified nature and faulting of the sediments in and around the deposit area has a strong effect on hydraulic conductivity, but may also result in a strong downward vertical gradient within the aquifer system. This vertical gradient is theorized to result in the deeper potentiometric surface observed in deeper wells. The horizontal gradient in this area is also relatively high, consistent with flow impeded by low hydraulic conductivity, with silicification apparently being a major factor.

On the south and east sides of the proposed Grassy Mountain Mine, faults appear to act as barriers to groundwater flow, but the true impact of faulting on groundwater flow is hard to differentiate from the effects of deposit silicification. The silicification and faulting seems to decrease the hydraulic conductivity of the arkosic sandstone but potentially increase the hydraulic conductivity of the underlying tuff. It is possible with the combination of the silicification, steeply dipping interbedded clay, siltstone, and sinter, and the faulting near the proposed Grassy Mountain Mine allows some groundwater from the proposed Grassy Mountain Mine to flow into (or through) the tuff.

The conceptual model includes the assumption that some faults act as barriers (Figure 21) and some act as conduits to flow (Figure 29). The presence of barriers was a possible explanation to explain negative boundaries observed during pumping tests The presence of conduits is based on the more productive zones in the highly silicified area based on drilling evidence. The wells with higher productivity maybe intersecting faults that are acting as conduits for groundwater flow.

Monitoring well GMW18-34 was drilled to better understand the aquifer within the deposit area. This is a dry well and cannot be test pumped to understand the potential impacts of faults to groundwater flow. Further drilling, evaluation of core, and testing of hydraulic parameters may reveal more precise information on where faulting is limiting, enhancing, or having no effect on the flow of groundwater. However, the groundwater conceptual model and estimates of dewatering for mining are unlikely to change in a meaningful way.

The Kern Basin Tuff, like the Grassy Mountain Formation, surfaces at higher elevations on the southern and eastern sides of Grassy Mountain and dip towards the north and northwest directions towards Negro Rock Canyon.

Groundwater flow in the Project area is generally from the southeast to the northwest, from higher elevations along the base of Grassy Mountain to lower elevations along Negro Rock Canyon. This flow direction is evident in both the shallow and deep potentiometric surfaces, a result that also supports a single aquifer system.

Downgradient of the proposed Grassy Mountain Mine, the strata are less silicified, and the horizontal and vertical gradients are not as pronounced. It is still likely that horizontal and vertical connectivity between zones within the aquifer is affected by low permeability, discontinuous, interbedded layers of clay and siltstone, as well as faults. Hydraulic conductivity is higher downgradient of the proposed Grassy Mountain Mine, but lithologic variations and faulting affect groundwater flow and occurrence. Hydraulic conductivity values downgradient of the proposed Grassy Mountain Mine derived from test pumping are on the order of 10^{-3} cm/s to 10^{-5} cm/s, representative of sandstone and conglomerate aquifers. Consistent piezometric head in wells completed at different elevations would suggest a single aquifer system.

The Grassy Mountain fault zone extending north of the proposed Grassy Mountain Mine acts like a barrier to groundwater flow based on testing of nearby wells; the most productive wells in the area are presumably located on the east side of the Grassy Mountain fault zone.

Discharge of the regional aquifer is assumed to be local springs and ultimately the Malheur River. The low total aggregate spring discharge in the hydrologic basin suggests a low groundwater recharge.

While limited in spatial extent and hydraulic connectivity, the water-bearing zones within the Grassy Mountain Formation are proposed to constitute a single, heterogeneous and locally complex aquifer system. This conclusion is supported by lithology, piezometric surface, and geochemical signature. The aquifer system is defined by low hydraulic conductivity and high hydraulic gradient in and near the proposed Grassy Mountain Mine and higher hydraulic conductivity and lower hydraulic gradient away from the deposit area. Groundwater conditions appear to be mostly influenced by silicification and/or faulting near the deposit area and sedimentary facies changes and faulting downgradient of the deposit area.

The geochemistry of the groundwater appears to be strongly influenced by lithology. The main regional aquifer displays a Na/K-HCO3 geochemical identity, associated with volcanic tuff and sedimentary deposits. Groundwater originating from volcanics shows a Ca-HCO3 signature. Water chemistry in the immediate vicinity and downgradient of the silicified zone where the mineralized deposit is located has an Na/K-SO4 geochemical identity. Groundwater in the immediate area of the mine has not only higher sulfate, but also higher concentrations of arsenic, boron, iron, manganese, molybdenum, and nickel compared to baseline water quality data from the rest of the area. However, arsenic is considered elevated throughout the study area with all groundwater monitoring locations and most of the tested springs exceeding the drinking water standard for arsenic.

Deep groundwater beneath the deposit also has the Na/K-SO4 identity. This is either a result of deeper mineralization or vertical transport of groundwater downward from the mineralized area of the deposit.

7 POTENTIAL AQUIFER IMPACTS DUE TO GROUNDWATER PRODUCTION

While they are not issues related to or required for characterization of baseline conditions, this study includes a preliminary characterization of potential impacts due to groundwater production and mine dewatering as an initial step in assessing these important impacts. Further preliminary evaluation of these impacts is also presented in Volume 3 of the Groundwater Baseline Conditions Report (SPF, 2021b).

In the Water Resources Study Area, the main use of groundwater currently is watering of livestock and wildlife from springs. Water production for mine dewatering and mine raw and process water for the Project has the potential for impacting springs and groundwater levels in the area. This section describes a hydrogeological and two-dimensional analytical modeling approach for evaluating groundwater pumping on groundwater levels. A numerical model has also been developed to assess impacts, the results of which are presented in a separate report.

7.1 Mine Dewatering

In general, wells completed in the silicified formation encompassing the deposit area produce minor water (on the scale of 1 gpm) or are dry. Testing of wells (59762 and GMW17-32) completed in silicified sediments near the deposit area indicate very low transmissivity and hydraulic conductivity values. GMW17-33 is completed in an apparent isolated section of less silicified material. Testing of this well initially indicated somewhat higher transmissivity values, but as the cone of depression expanded, the drawdown significantly increased indicating a low transmissivity value in the surrounding media. During testing of these wells, no response was observed in any of the nearby monitoring wells, but a delayed response has been observed in GW-3 located west and away from the silicified proposed Grassy Mountain Mine.

Testing and the response in nearby wells suggest a heterogeneous system of low permeability and limited hydraulic connectivity. The dewatering required for the mining operation should be minor (tens of gallons per minute) given the characteristics of the proposed Grassy Mountain Mine, but there is the possibility of encountering compartmentalized zones of less silicified materials producing more water or faulting acting as conduits for groundwater flow. If such zones are encountered during the mining operation, higher dewatering flows may be required, but for a short duration (on the scale of days). Given the expected low dewatering requirements and silicified zones acting as hydraulic barriers, only minor impacts to the regional aquifer system are anticipated.

7.2 Production of Mine Process Water

Water is required for the Project for mining, ore processing, fire protection, potable uses, dust suppression, and various other uses. Raw water will be pumped from the groundwater wells to a raw water storage tank, and then piped for use at the Project. It is anticipated that dust suppression uses can be supplied directly from existing wells.

The anticipated total peak raw water demand in the summer when water cannot be reclaimed from the tailings storage facility is 200 gpm. During the rest of the year, the average annual daily demand is on the order of 50 gpm.

An aquifer test was performed on PW-4 from November 28 to December 4, 1989. PW-4 was pumped at a constant discharge rate of 145 gpm for 4,530 minutes (approximately 3.14 days) with water level measurements taken in PW-4 and nearby GW-4 during pumping and for approximately 4 days of recovery. The semi-logarithmic plots (Figure 43 &Figure 44) of the drawdown of both PW-4 and GW-4 indicate the cone of depression had reached a negative boundary at approximately 1,000 minutes pumping.

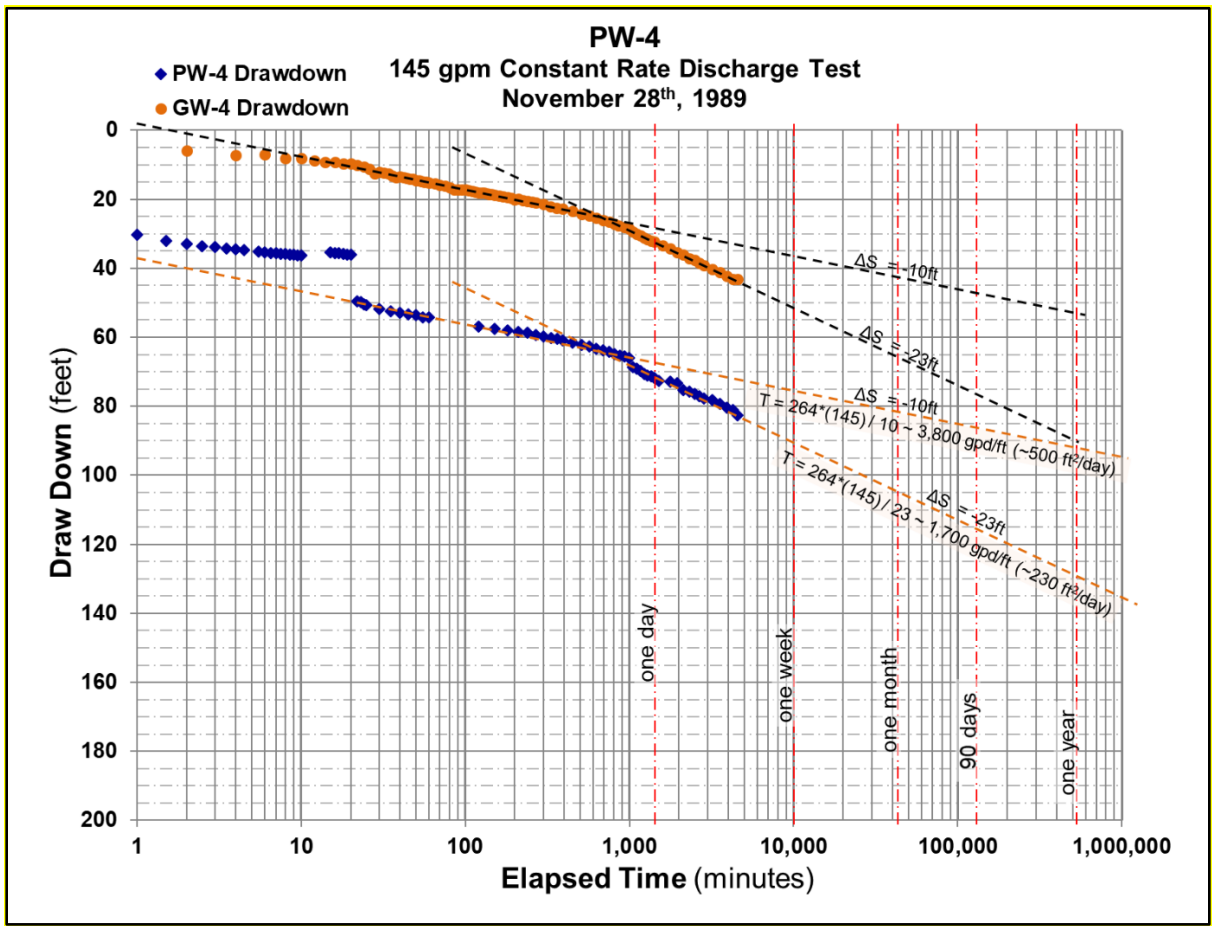

Figure 43. PW-4 Aquifer Test Semi-Logarithmic Plot

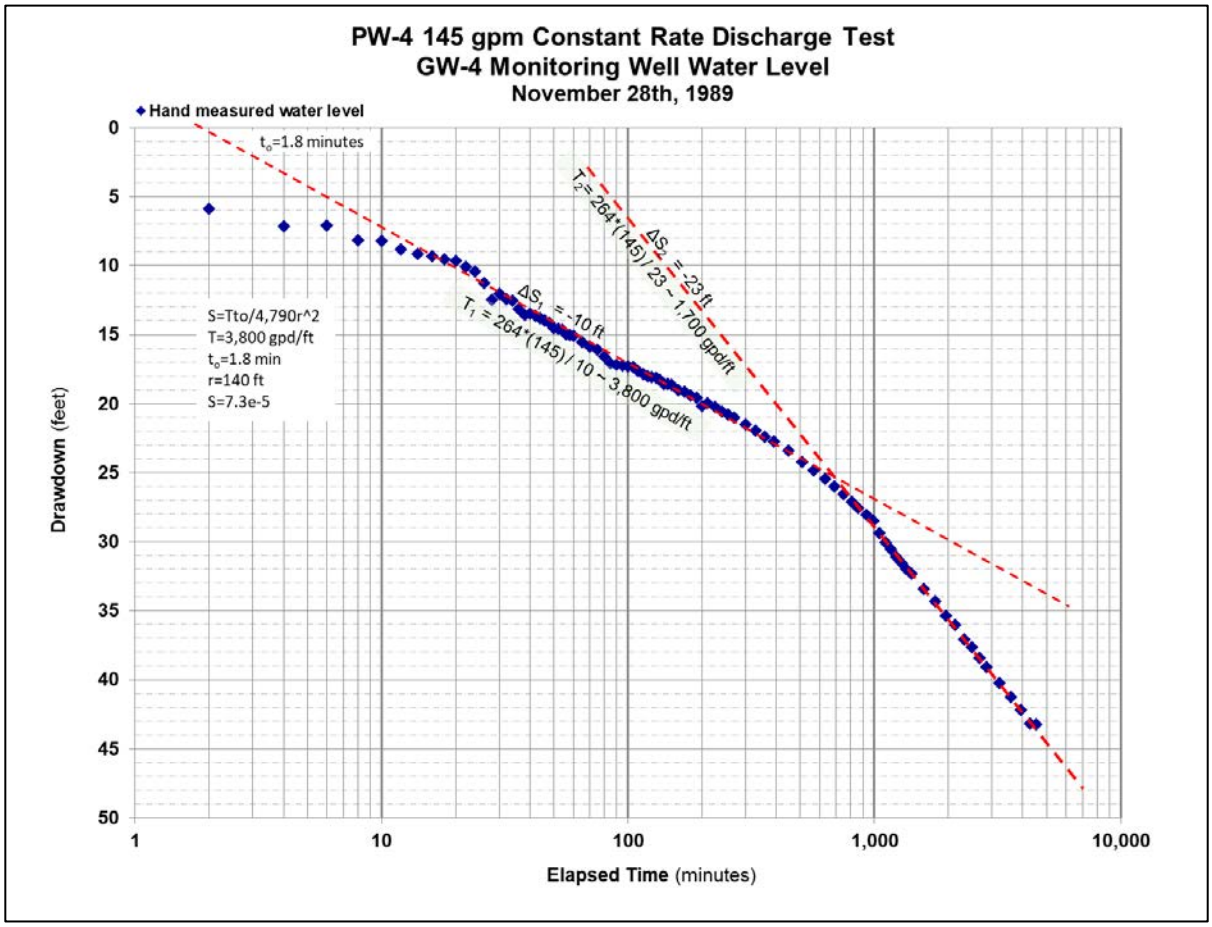

Figure 44. PW-4 Aquifer Test, GW-4 Drawdown

The flow and drawdown data from both wells were analyzed using the Cooper-Jacob straight line technique to obtain the near well transmissivity of approximately 500 ft^2/day and storativity value of approximately $7.0e^{-5}$. The initial 22 minutes of the test were not matched due to a large increase in drawdown due to what appears to be the flow being increased to 145 gpm. This storativity value is on the lower-end of the range for confined aquifers of 0.005 to 0.00005 (Freeze and Cherry, 1979).

Using these transmissivity and storativity values to calculate drawdowns at various times and distances using a Theis[11] analysis results in an unreasonably large area of influence. For

[11] The Theis method (Theis, 1935) is commonly used by hydrologists for evaluating potential impacts of groundwater pumping. Assumptions inherent to the use of the non-equilibrium Theis equation are that the aquifer is homogeneous and isotropic, uniform in thickness and with infinite areal extent, the aquifer receives no recharge, the pumping well penetrates the full aquifer thickness, water removed by discharge is removed instantaneously, the pumping well is 100 percent efficient, laminar flow

example, predicted drawdown at a distance of one mile after one year of pumping at 320 gpm is 48 to 78 feet. In the instance of PW-4, however, the negative boundary shown in the drawdown data indicates compartmentalization of the aquifer. With the amount of complex faulting and variations in aquifer thickness and areal extent causing compartmentalization of the aquifer, it is more reasonable to expect a smaller area of influence but possibly a greater impact on groundwater levels in the near vicinity of the pumping well. It is also likely that drawdown from long-term pumping in the confined portions of the aquifer will induce leakage from unconfined portions of the aquifer with much higher storativity values. It is also possible that drawdown within the compartments will induce flow across boundaries from outside of the compartments, resulting in some drawdown outside of the compartments and decreasing drawdown within the compartments.

Under a compartmentalized aquifer scenario, where drawdown effects from confined aquifers eventually propagate upward into unconfined portions of the aquifer, the magnitude of drawdowns can also be qualitatively estimated based on pumping volumes. For example, assuming wells draw from one or more compartmentalized zones located within a circular area two miles in diameter centered on PW-4, the total area of the aquifers would be approximately 2000 acres. Further assuming pumping of 1 acre-foot per day (225 gpm) for 10 years, the total volume pumped would be 3,650 acre-feet. Lastly, assuming a specific yield of 0.10 for sediments within the zone of influence, the average drawdown would be 18 feet. Drawdowns would be greater near pumping wells and less at the margins of the compartmentalization. This analysis is not meant as a prediction of actual drawdowns, but rather to put the magnitude of potential drawdown in perspective. The actual extent of drawdown impacts cannot be predicted with existing data because the areal extent and geometry of the compartmentalized zones tapped by PW-4 or future production wells has not been determined. Future wells will be tested pumped for extended durations to evaluate aquifer sustainability and to access impacts on groundwater levels in the vicinity of the pumping wells.

An alternative method to evaluate the potential for pumping impacts on springs is by comparing geochemistry of individual wells and springs. PW-4 is located near (within 2 miles) of Poison Spring, Lowe Spring, Government Corral Spring, Deposit Stock Tank and Tank East of Negro Rock. There are multiple faults and lithologic facies mapped between these springs and PW-4. The geochemical characteristics of Sagebrush Spring, Government Corral Spring, and Deposit Stock Tank suggest that these springs originate from the volcanic sections of the aquifer, which is different from the geochemical characteristics in the area of PW-4. The different water chemistry, combined with mapped faults and lithologic facies changes, make it less probable that pumping near PW-4 would affect these springs. Poison Spring and Lowe Spring, however, have a similar geochemical signature as PW-4. This may suggest an increased chance of Poison Spring and Lowe Spring being affected by pumping near PW-4.

exists throughout the aquifer, and that the water table or potentiometric surface has no slope. These assumptions are never completely satisfied under field conditions.

Lastly, the location of springs provides insight into the potential for impacts due to construction of a well field in the vicinity of PW-4. Referring back to Figure 7, it seems unlikely that pumping in the vicinity of PW-4 will have a measurable impact on springs to the south of mine area such as Upper and Lower Sourdough Spring, Twin Springs, Whiskey Spring, Oxbow Spring, and Oxyoke Spring. These springs are five miles or more distant from PW-4. This distance, combined with known and unknown structural and lithologic barriers, should attenuate pumping impacts. In contrast, springs at distances of less than two miles from PW-4, such as Poison Spring, the Tank East of Negro Rock, and Lowe Spring, are more likely to be impacted by pumping in the PW-4 vicinity.

8 CONCLUSIONS

8.1 Aquifer System

The aquifer system within the Grassy Mountain Project Area is characterized by the following:

- Groundwater is found within permeable sediments and fractured rock within the Project Area. The Grassy Mountain Formation, consisting of arkosic sandstone, conglomerate, and tuffaceous siltstone is the primary water-bearing unit.

- Although there are different piezometric surfaces near and within the deposit area, available data suggest a single aquifer system with high vertical gradients in upland areas, including the vicinity of the deposit area.

- Groundwater elevations in most wells within the project area are relatively stable over time, based on a monitoring period that spans several years. Some wells show influence of seasonal recharge, particularly during periods of above average precipitation. Other wells show fluctuations attributed to groundwater pumping or to drilling activities.

- Groundwater flow is to the northwest, from areas of higher to lower ground surface elevation.

- Potentiometric surface maps based on wells and VWPs support a consistent flow direction without seasonally influenced variations. The pattern of groundwater flow shows local variations attributed to the presence of faults, fractures, lithologic facies changes, vertical gradients, or some combination of these influences.

- Aquifer hydraulic conductivity is low within the immediate vicinity of the Grassy Mountain ore body, attributed low permeability materials (i.e., clay and siltstone, competent bedrock, and silicified deposits). Faults appear to generally function as negative hydraulic boundaries. Spatially discontinuous aquifer zones with higher permeability are apparent, particularly to the north of the deposit area, based on

borehole drilling and aquifer testing. However, the apparent higher permeability is also thought to reflect compartmentalized aquifer conditions, within an overall aquifer of lower, aggregate permeability.

- The low hydraulic conductivity in the vicinity of the deposit area is anticipated to significantly restrict groundwater flows into underground mine workings. Groundwater supply for mining purposes will need to be developed away from the silicified zones in the proximity of the ore body.

8.2 Water Quality

- Arsenic is present in groundwater within the Grassy Mountain vicinity. Concentrations exceeded the drinking water MCL at all of the 15 sampled well locations and at 8 of the 11 sampled spring locations. Higher arsenic concentrations occur hydraulically downgradient of the proposed Grassy Mountain Mine and are likely due to mineralized areas associated with the ore body.

- Other exceedances of the drinking water MCL included antimony (two samples), chromium (one sample), and lead (two samples).

- Groundwater within the Grassy Mountain vicinity exhibits different water quality types (Ca-HCO3, Na/K-HCO3, or Na/K-SO4) based on spatial distribution, attributed to subsurface lithology/facies characteristics and proximity to the proposed Grassy Mountain Mine.

- Groundwater with the Na/K-SO4 signature are located within and downgradient of the mineralized zone that will be mined. The sulfate, as well as concentrations of other constituents including arsenic that are elevated compared to regional background, is likely due to oxidation of minerals in the ore deposit to be mined. One of the wells in this area (the BLM well) also exhibits a slightly lower pH (in the range of 6 to 7) than regional background (typically pH > 8).

8.3 Recommendations

Paramount, Calico and SPF recommend that baseline characterization efforts be considered complete based on the data compilation and results of investigations performed at the Grassy Mountain Project Area with respect to groundwater characterization.

While not related to baseline characterization, further characterization of impacts from mining such as drawdown due to pumping groundwater for makeup and also from dewatering the mine, is recommended. In addition, projections of impacts to groundwater quality and flow during the post-mining and closure period should be performed. Such characterization studies are currently underway.

Cross Section B

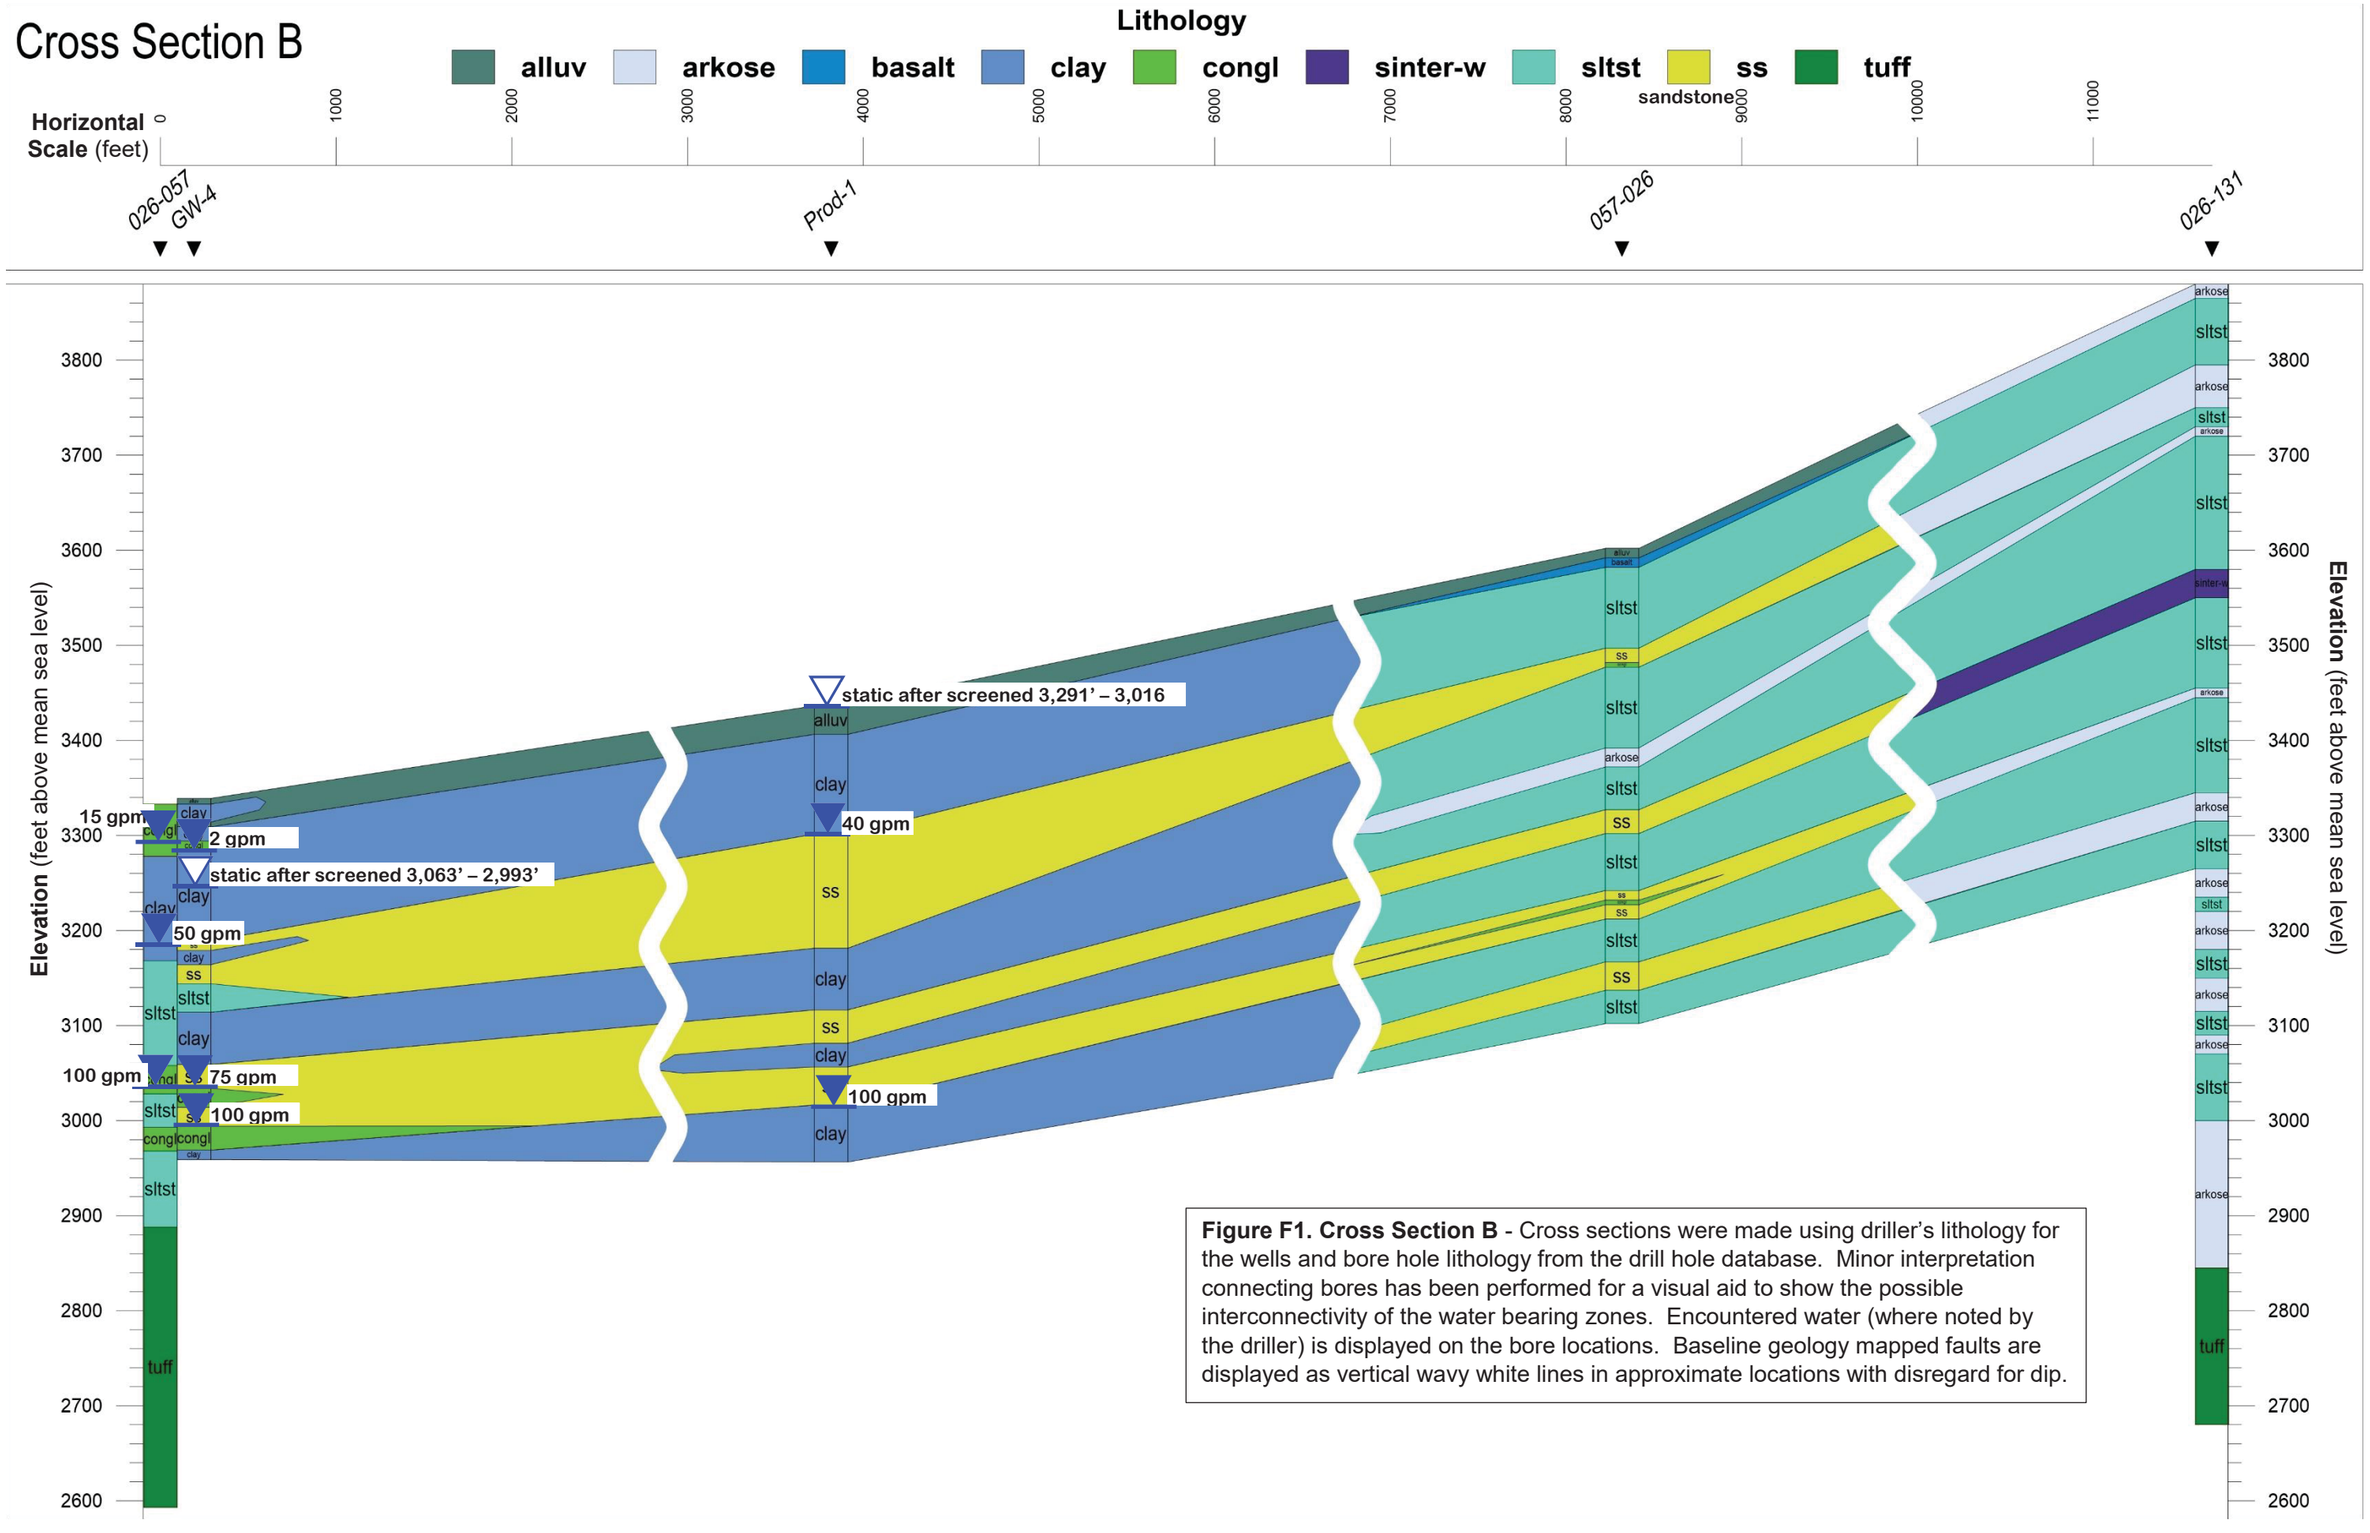

Figure F1. Cross Section B - Cross sections were made using driller's lithology for the wells and bore hole lithology from the drill hole database. Minor interpretation connecting bores has been performed for a visual aid to show the possible interconnectivity of the water bearing zones. Encountered water (where noted by the driller) is displayed on the bore locations. Baseline geology mapped faults are displayed as vertical wavy white lines in approximate locations with disregard for dip.

Cross Section C

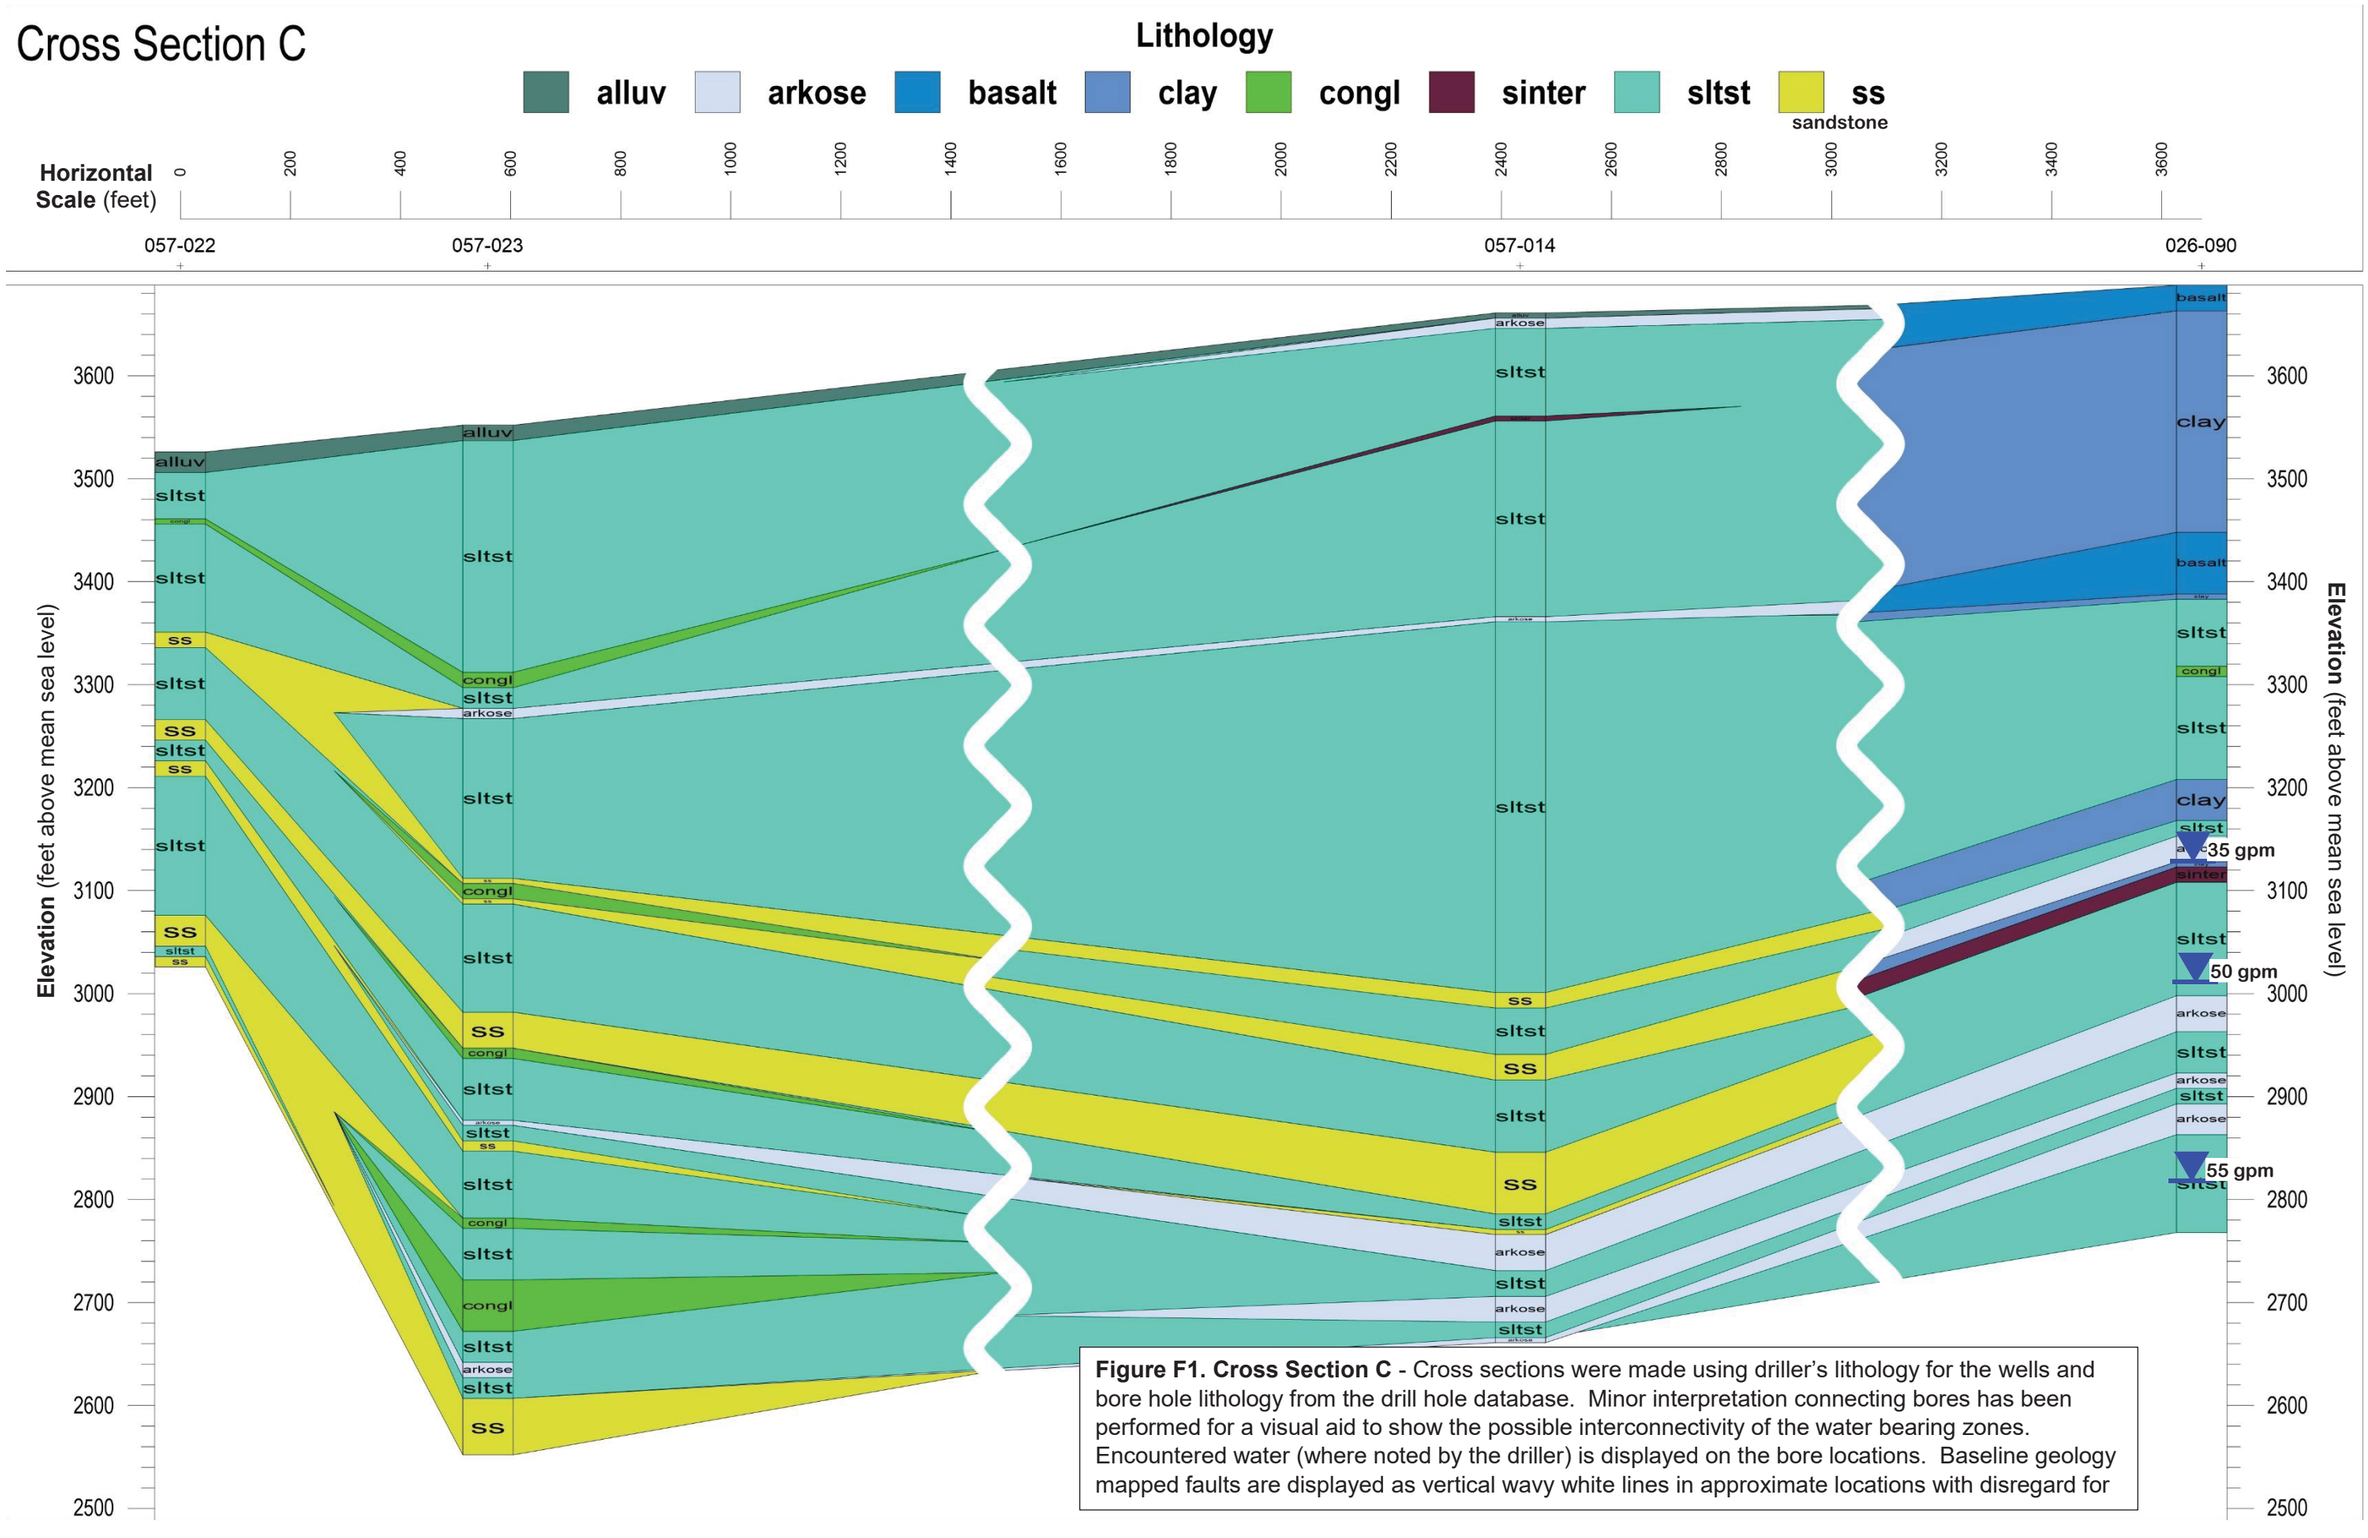

Figure F1. Cross Section C - Cross sections were made using driller's lithology for the wells and bore hole lithology from the drill hole database. Minor interpretation connecting bores has been performed for a visual aid to show the possible interconnectivity of the water bearing zones. Encountered water (where noted by the driller) is displayed on the bore locations. Baseline geology mapped faults are displayed as vertical wavy white lines in approximate locations with disregard for

Cross Section D

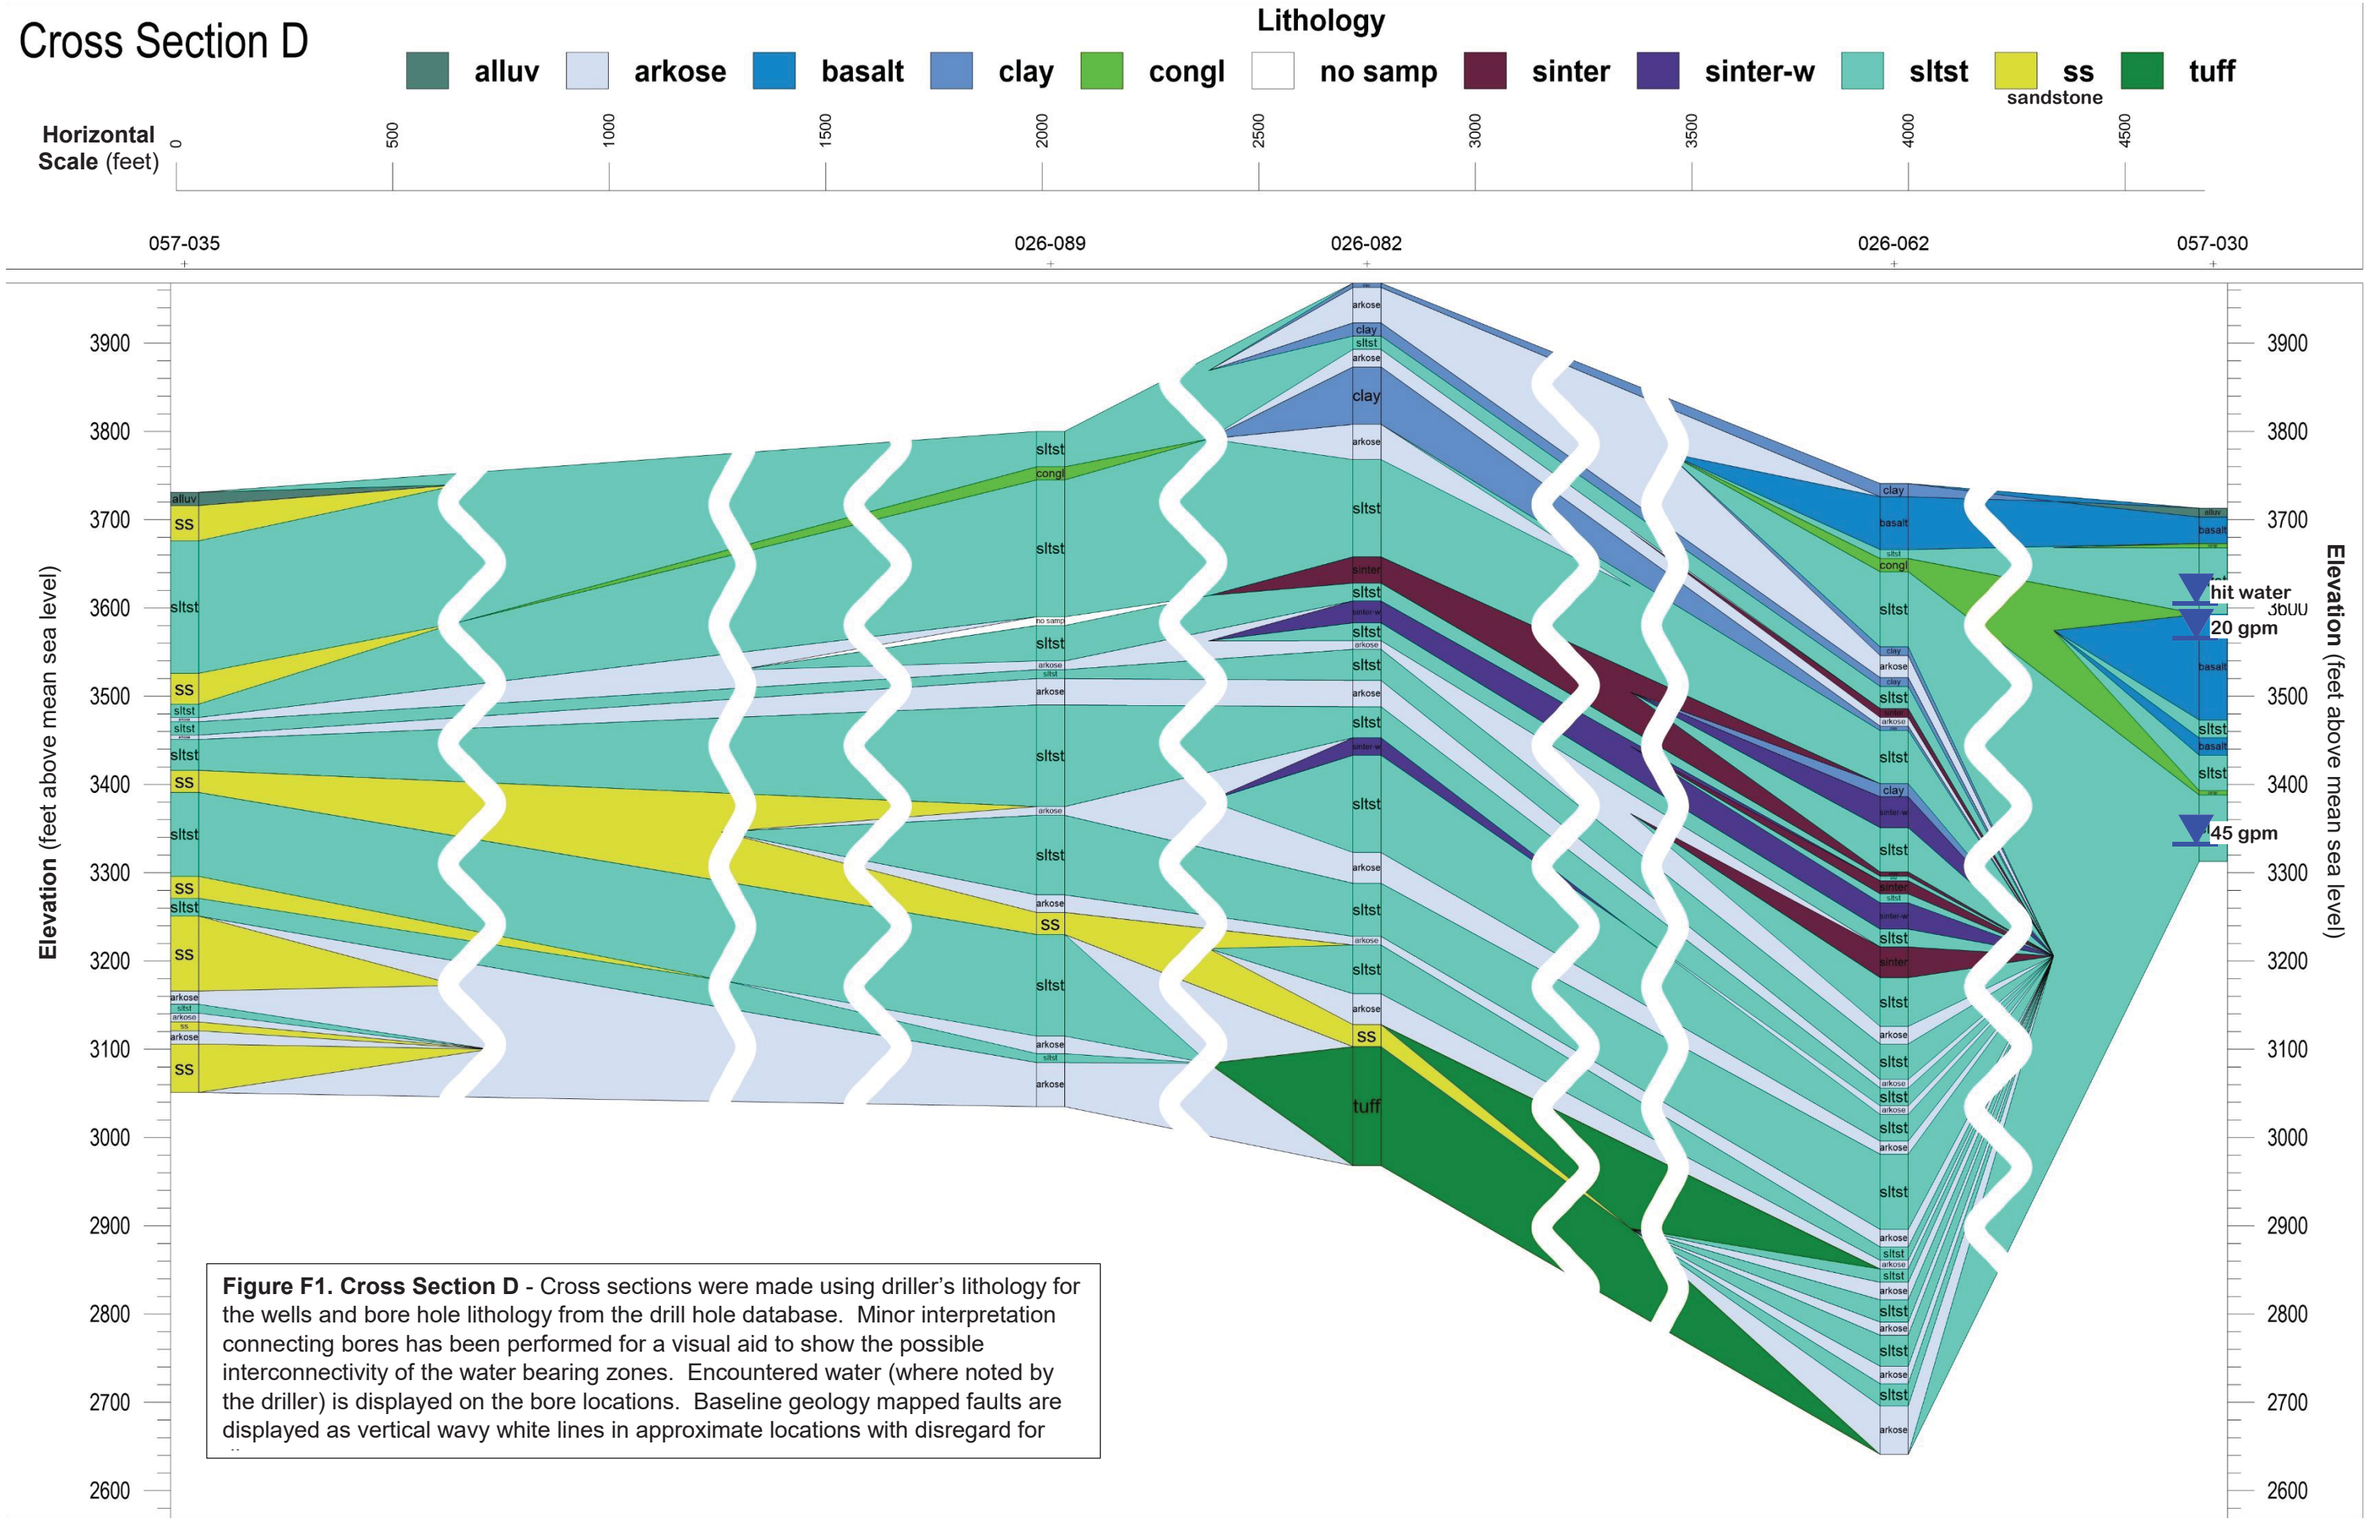

Figure F1. Cross Section D - Cross sections were made using driller's lithology for the wells and bore hole lithology from the drill hole database. Minor interpretation connecting bores has been performed for a visual aid to show the possible interconnectivity of the water bearing zones. Encountered water (where noted by the driller) is displayed on the bore locations. Baseline geology mapped faults are displayed as vertical wavy white lines in approximate locations with disregard for

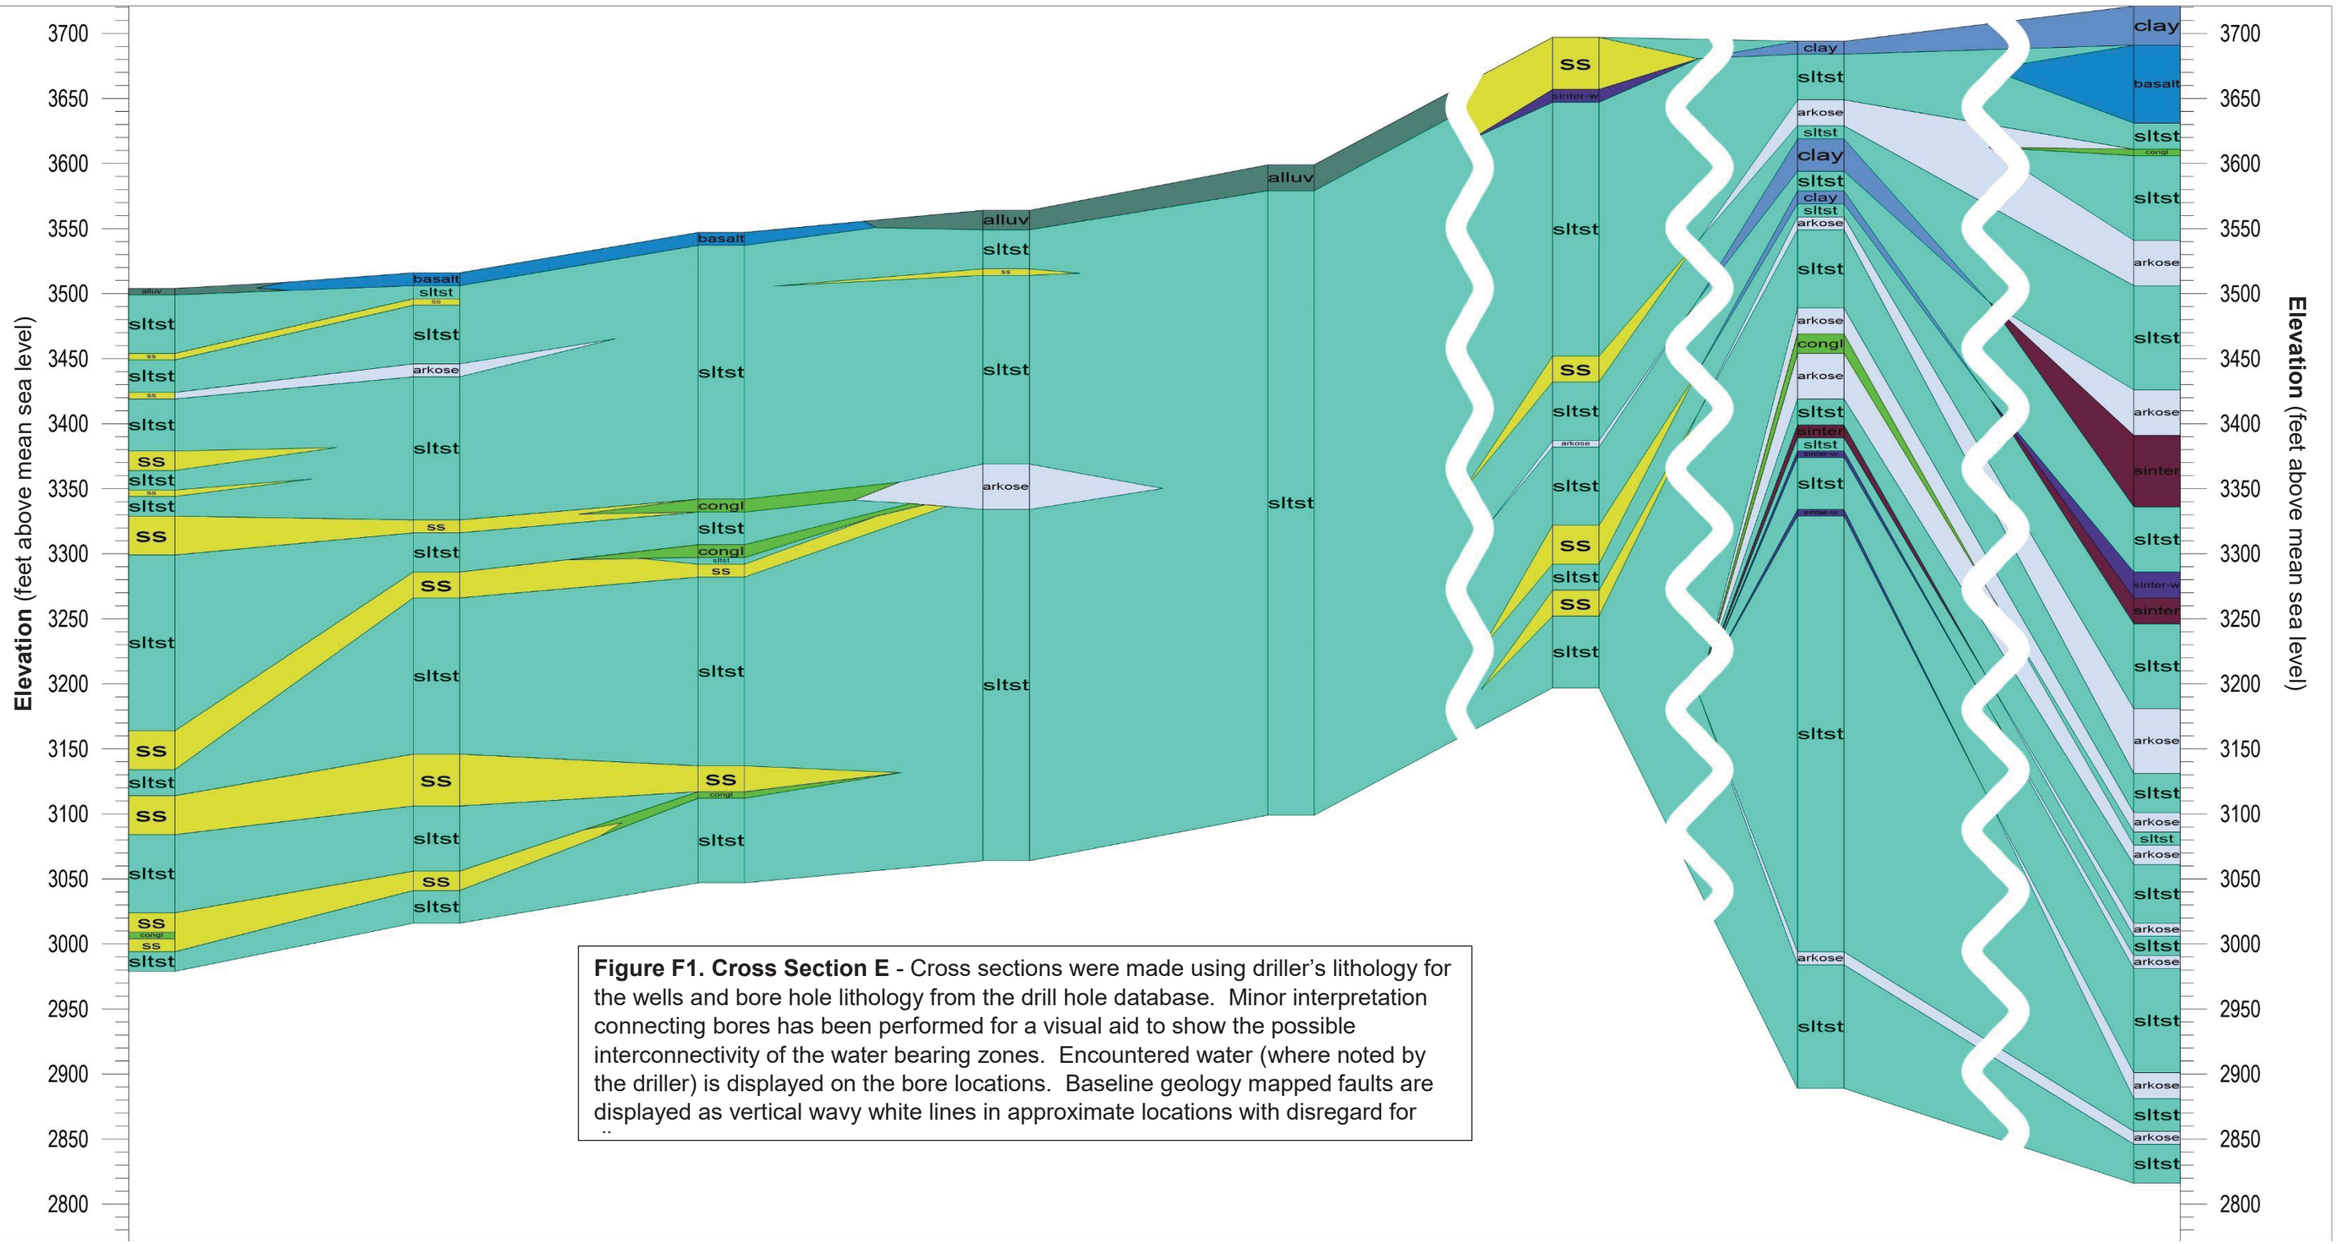

Figure F1. Cross Section E - Cross sections were made using driller's lithology for the wells and bore hole lithology from the drill hole database. Minor interpretation connecting bores has been performed for a visual aid to show the possible interconnectivity of the water bearing zones. Encountered water (where noted by the driller) is displayed on the bore locations. Baseline geology mapped faults are displayed as vertical wavy white lines in approximate locations with disregard for

Cross Section F

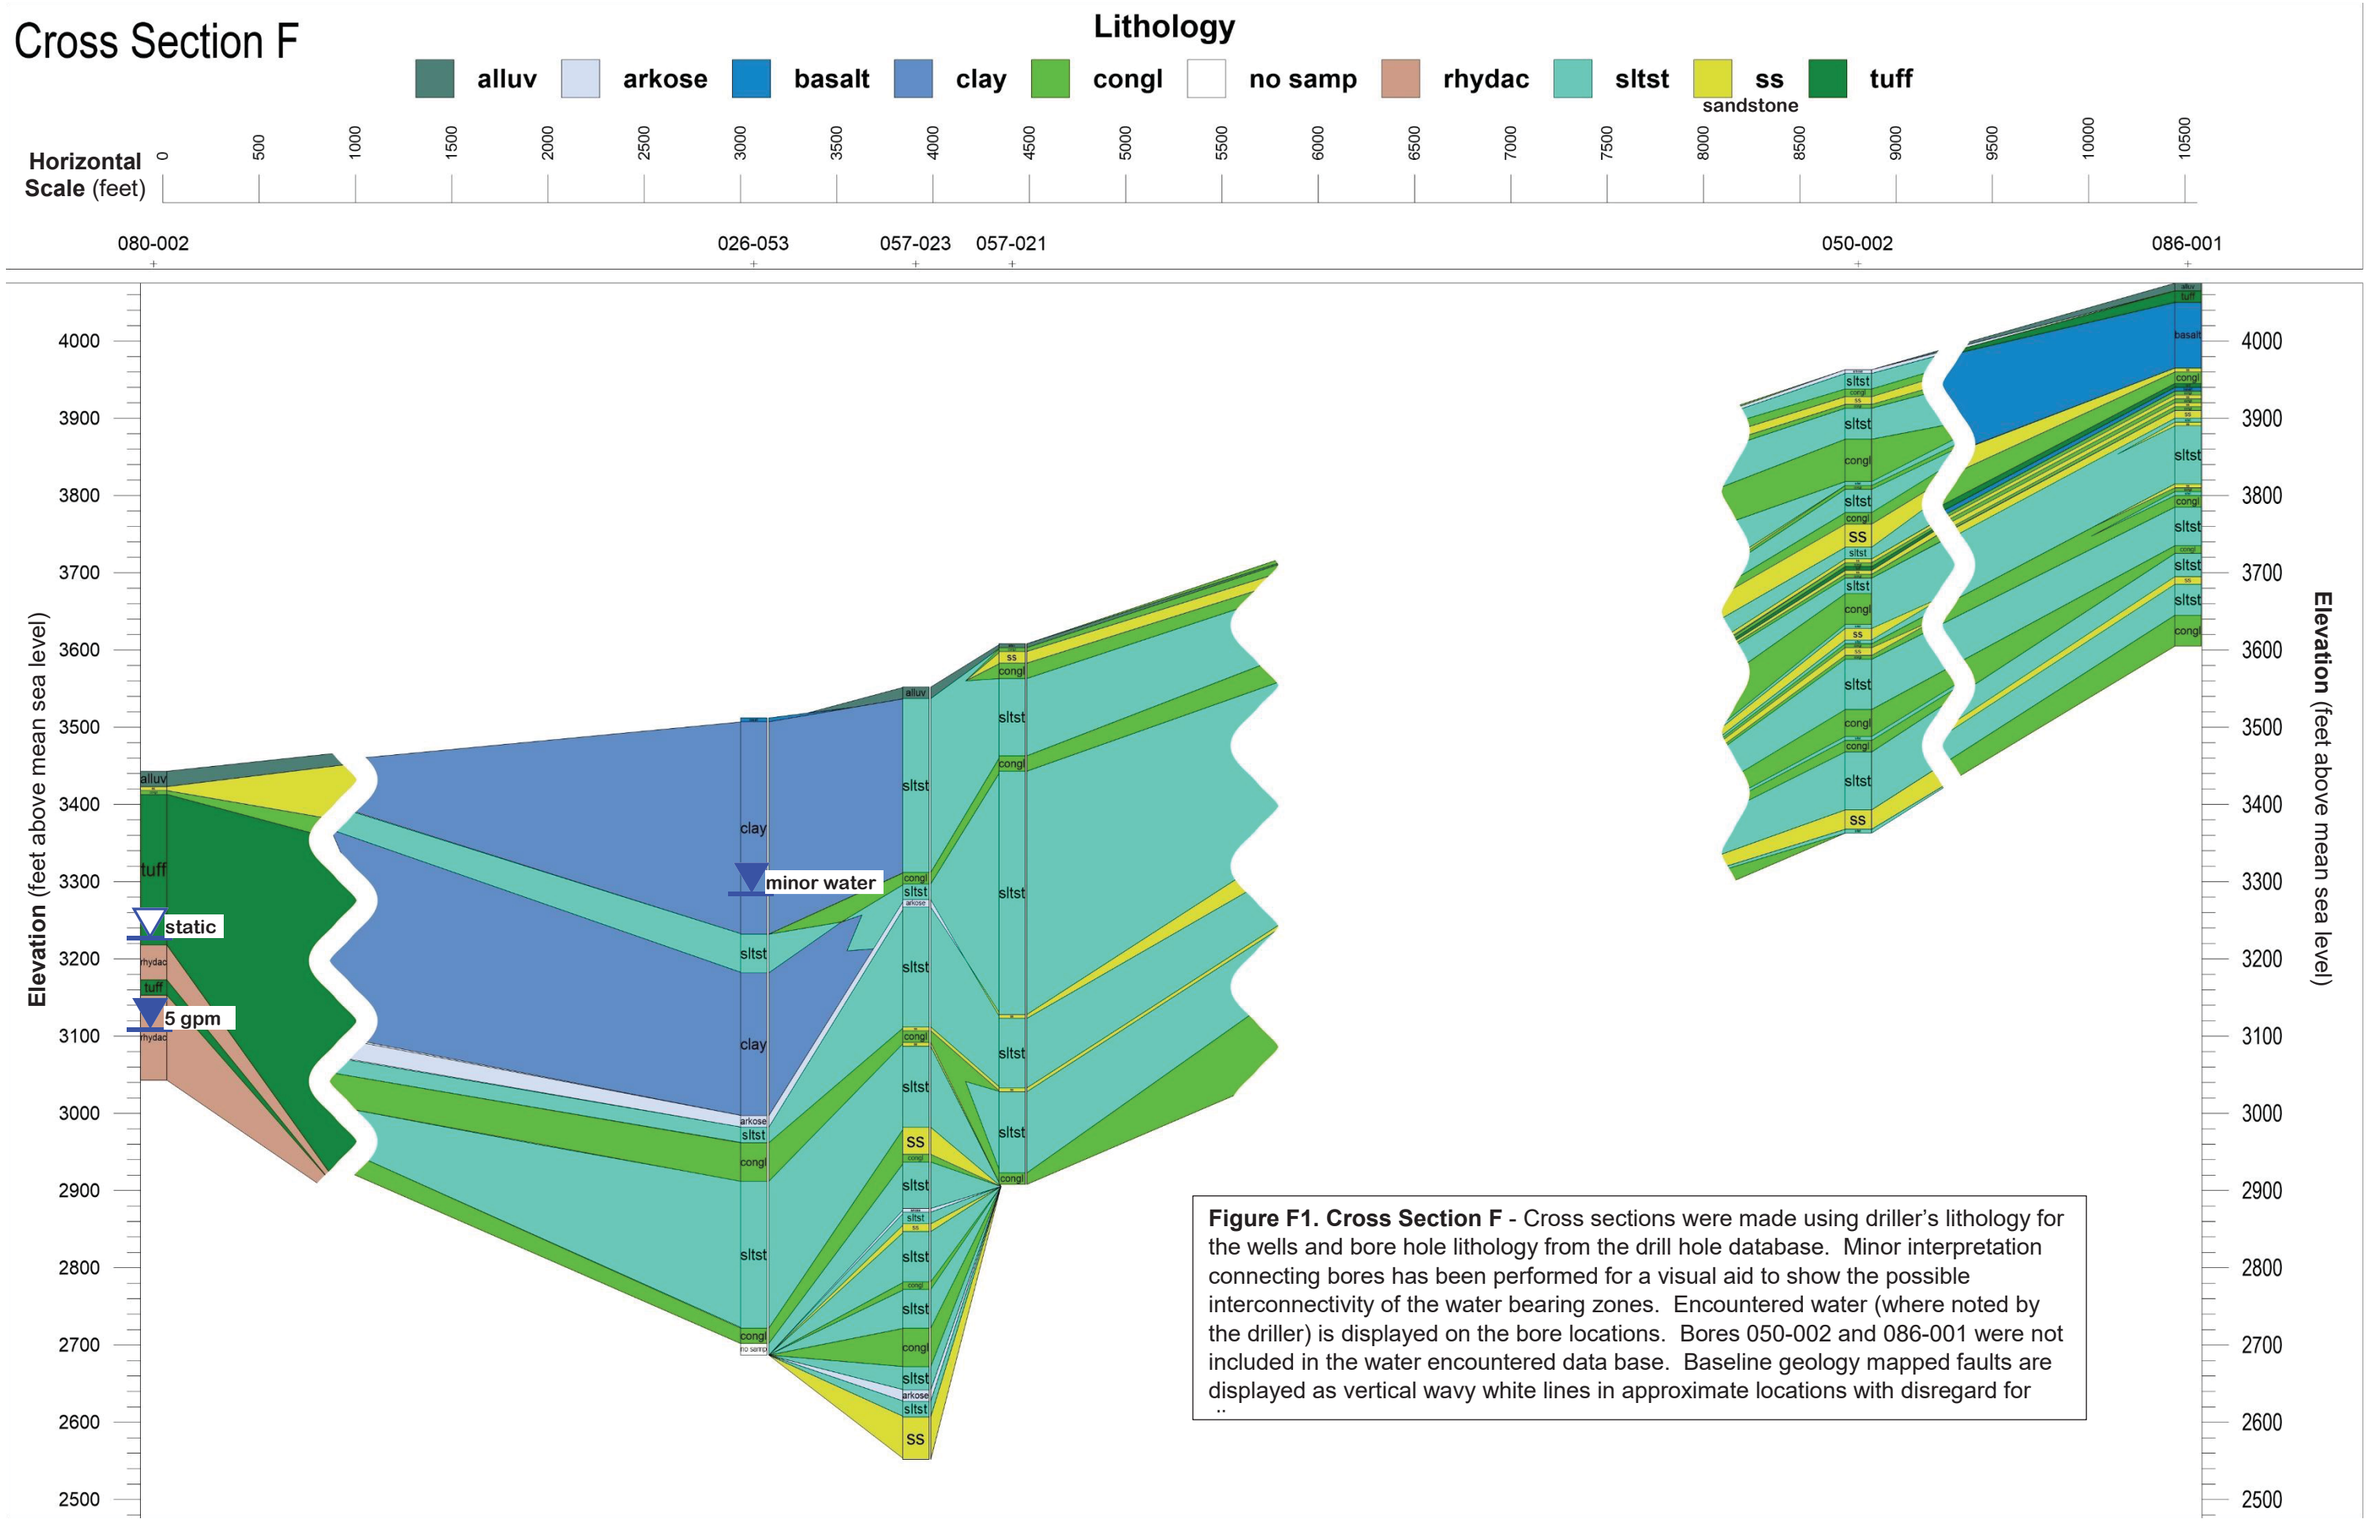

Figure F1. Cross Section F - Cross sections were made using driller's lithology for the wells and bore hole lithology from the drill hole database. Minor interpretation connecting bores has been performed for a visual aid to show the possible interconnectivity of the water bearing zones. Encountered water (where noted by the driller) is displayed on the bore locations. Bores 050-002 and 086-001 were not included in the water encountered data base. Baseline geology mapped faults are displayed as vertical wavy white lines in approximate locations with disregard for

Cross Section G

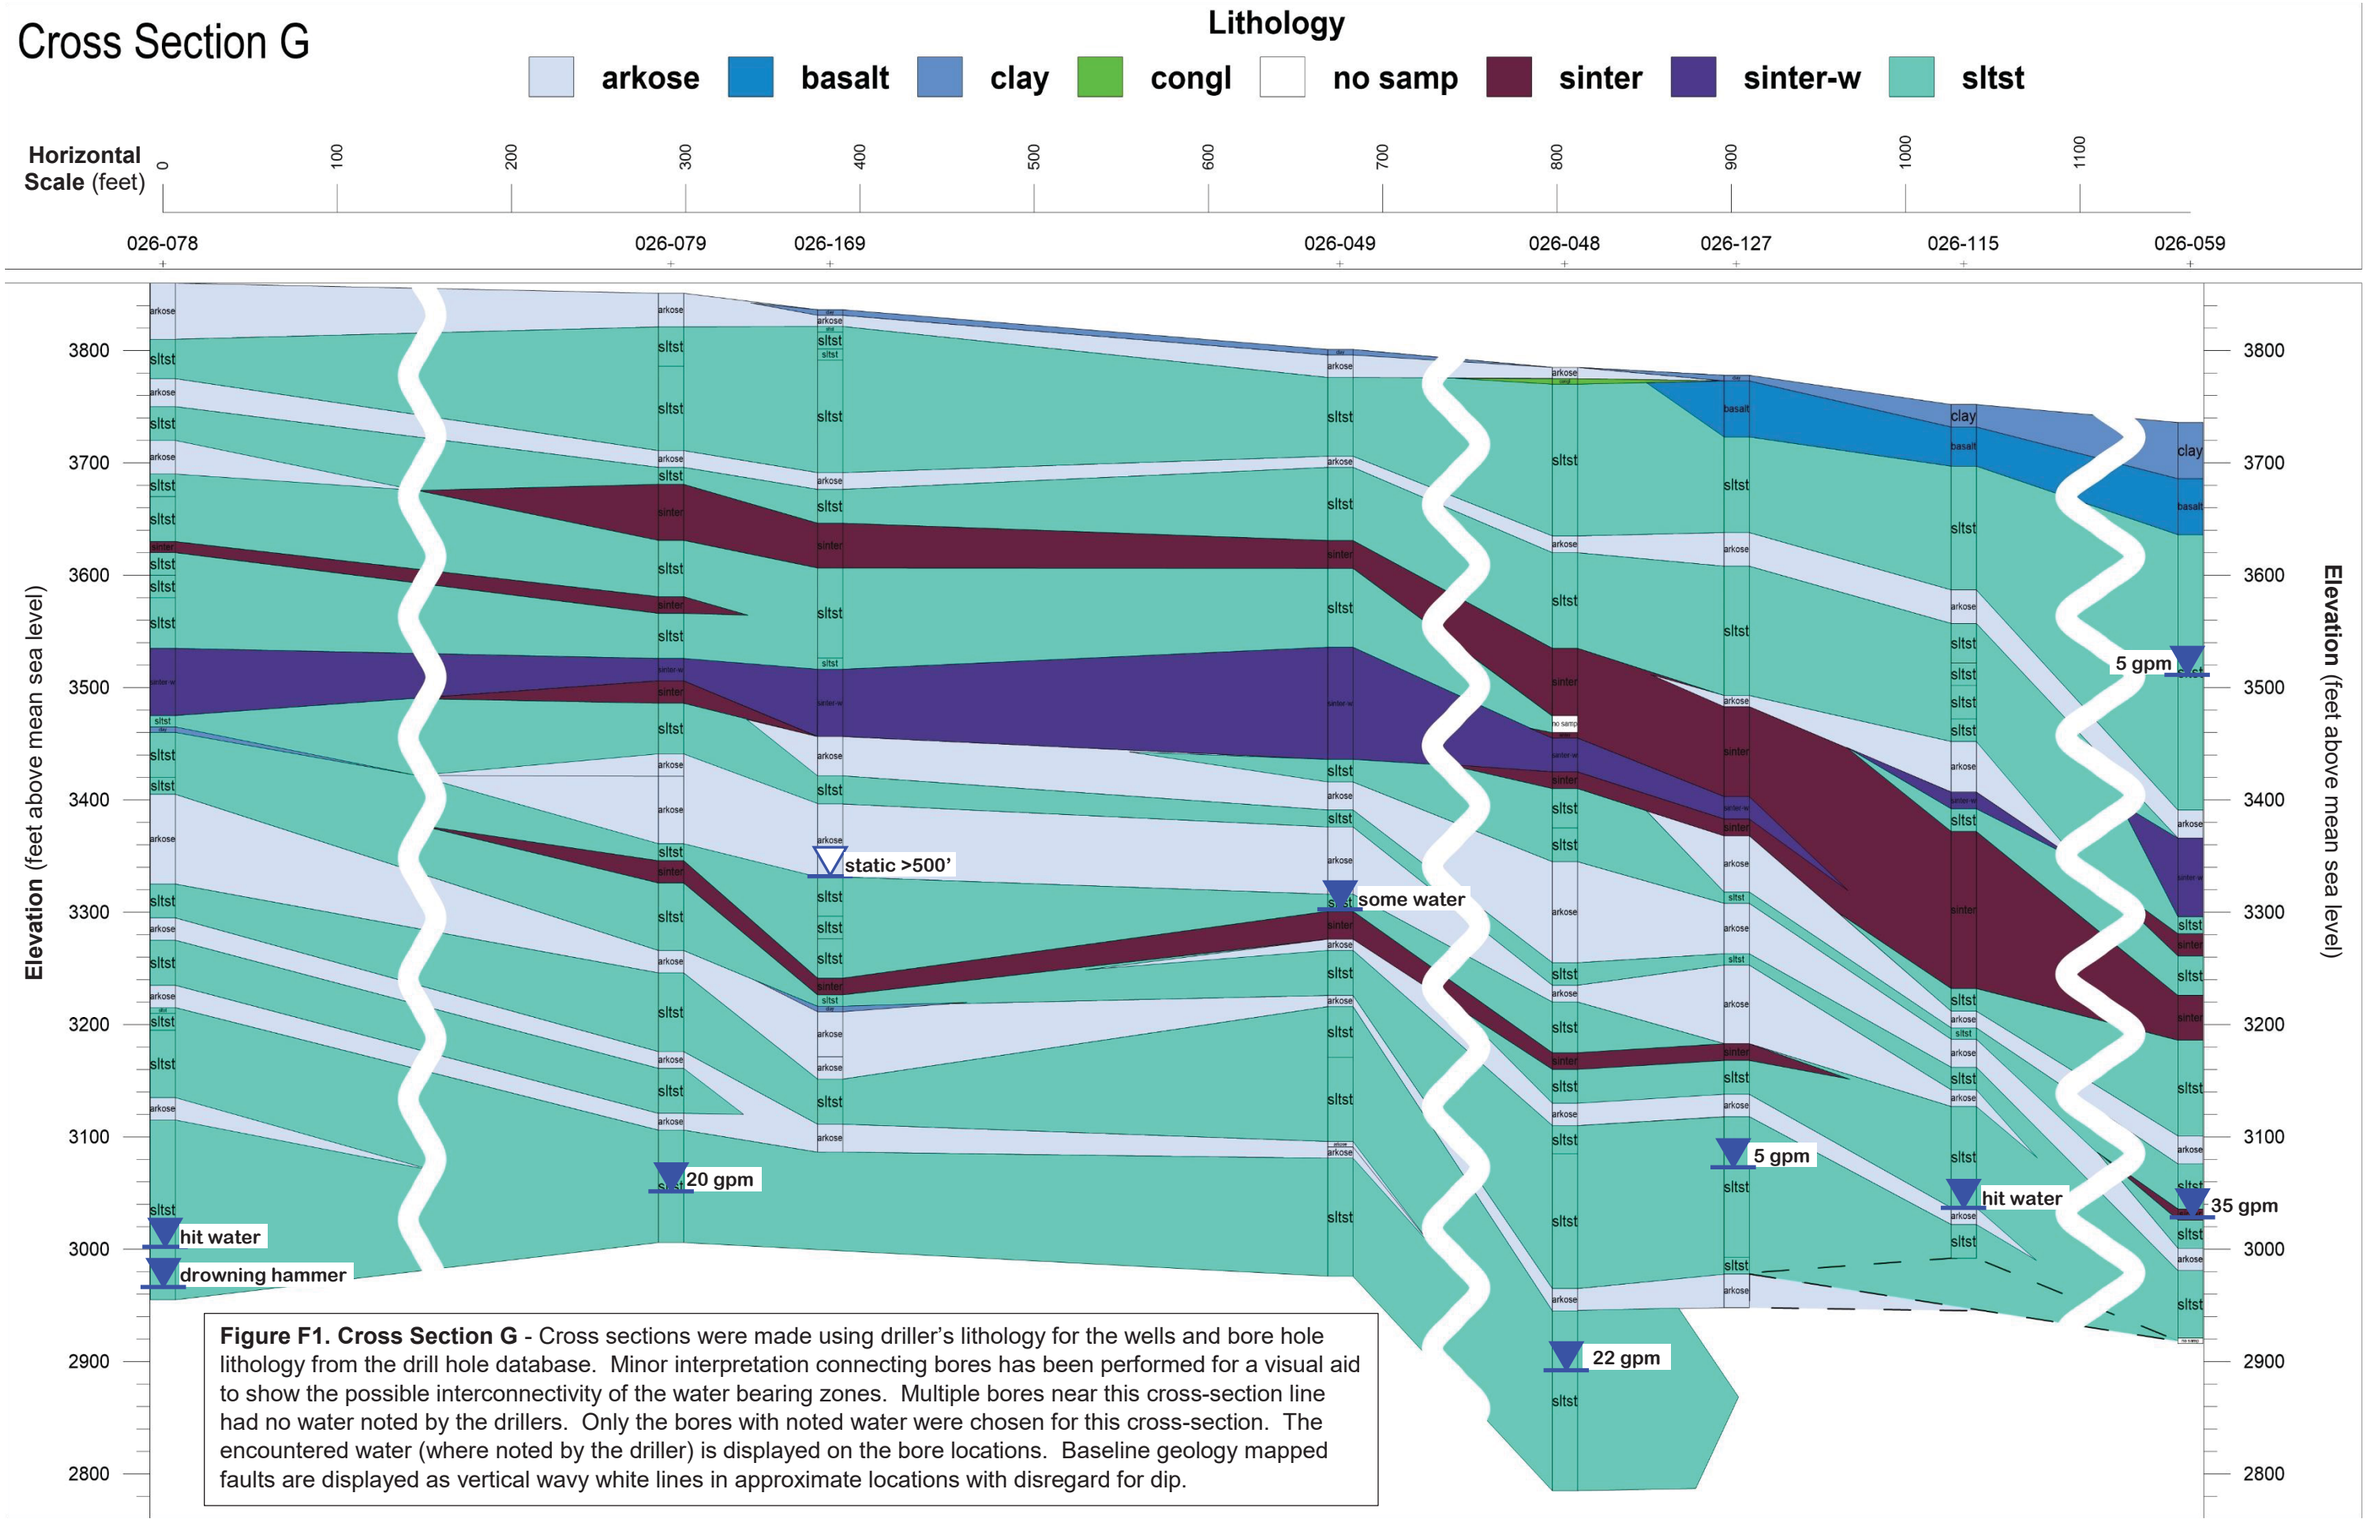

Figure F1. Cross Section G - Cross sections were made using driller's lithology for the wells and bore hole lithology from the drill hole database. Minor interpretation connecting bores has been performed for a visual aid to show the possible interconnectivity of the water bearing zones. Multiple bores near this cross-section line had no water noted by the drillers. Only the bores with noted water were chosen for this cross-section. The encountered water (where noted by the driller) is displayed on the bore locations. Baseline geology mapped faults are displayed as vertical wavy white lines in approximate locations with disregard for dip.

These contour maps are based on all available water level data including VWP and drill hole data. 100-foot contours are presented at regional scale (left) and 50-foot contours are presented for the deposit area (right). The water levels presented in these figures are represented in cross-sections H through K. Water level contours presented in section 4.6 are based entirely on monitoring well data excluding VWP and drill hole data. This was due to uncertainty of water levels in the deposit area and allowed for the potential of higher water level elevations based on up gradient from the deposit area. The contours were developed with the use of two control points within the western part of the deposit area and at GMW18-34 in order to not represent higher water levels where dry holes were present.

Ground Elevation

Material	From	To	SWL
General geology of the area consists of a series of intercalated sedimentary and volcanic formations of late Tertiary age. This well was originally drilled as an exploratory hole in 1988 or 1989. The hole was drilled to a total depth of 915 feet. OWRD staff sounded the well to a depth of 93 feet in 2012. The well could be blocked, or it may have collapsed. Construction at land surface consists of a 2" gray plastic casing inside of an 8.5" steel casing.			

Date started Completed 12/31/1989

WATER WELL REPORT

Bishop Well / MALH 54046

STATE OF OREGON
(Please type or print)
(Do not write above this line)

State Well No. #13
State Permit No.

(1) OWNER:

Name John Bishop
Address Vale, Oregon

(2) TYPE OF WORK (check):

New Well ☒ Deepening ☐ Reconditioning ☐ Abandon ☐
If abandonment, describe material and procedure in Item 12

(3) TYPE OF WELL:

Rotary ☐ Driven ☐
Cable ☒ Jetted ☐
Dug ☐ Bored ☐

(4) PROPOSED USE (check):

Domestic ☐ Industrial ☐ Municipal ☐
Irrigation ☐ Test Well ☐ Other ☐

(5) CASING INSTALLED:

Stock
Threaded ☐ Welded ☒

12 Diam. from 1 ft. to 150 ft. Gage .250
" Diam. from ft. to ft. Gage
" Diam. from ft. to ft. Gage

(6) PERFORATIONS:

Perforated? ☒ Yes ☐ No.
Type of perforator used Torch
Size of perforations in. by in.
18' perforations from 135 ft. to 145 ft.
perforations from ft. to ft.
perforations from ft. to ft.

SCREENS:

Well screen installed? ☐ Yes ☒ No
Manufacturer's Name
Type Model No.
Diam. Slot size Set from ft. to ft.
Diam. Slot size Set from ft. to ft.

(8) WELL TESTS:

Drawdown is amount water level is lowered below static level
Was a pump test made? ☐ Yes ☐ No If yes, by whom?
Yield: gal./min. with ft. drawdown after hrs.
" " " "
" " " "
Bailer test gal./min. with ft. drawdown after hrs.
Artesian flow g.p.m.
Temperature of water Depth artesian flow encountered ft.

(9) CONSTRUCTION:

Well seal—Material used
Well sealed from land surface to ft.
Diameter of well bore to bottom of seal in.
Diameter of well bore below seal in.
Number of sacks of cement used in well seal sacks
Number of sacks of bentonite used in well seal sacks
Brand name of bentonite
Number of pounds of bentonite per 100 gallons of water lbs./100 gals.
Drive shoe used ☒ Yes ☐ No Plugs Size: location ft.
Any strata contain unusable water? ☐ Yes ☒ No
Type of water? depth of strata
Method of sealing strata off
Was well gravel packed? ☐ Yes ☒ No Size of gravel:

(10) LOCATION OF WELL:

County Malheur Driller's well number
¼ ¼ Section T. R. W.M.
Bearing and distance from section or subdivision corner

(11) WATER LEVEL: Completed well.

Depth at which water was first found ft.
Static level 95 ft. below land surface. Date 6/15/6
Artesian pressure lbs. per square inch. Date

(12) WELL LOG:

Diameter of well below casing 12"
Depth drilled 482 ft. Depth of completed well 432 ft.

Formation: Describe color, texture, grain size and structure of materials and show thickness and nature of each stratum and aquifer penetrated, with at least one entry for each change of formation. Report each change in position of Static Water Level and indicate principal water-bearing strata.

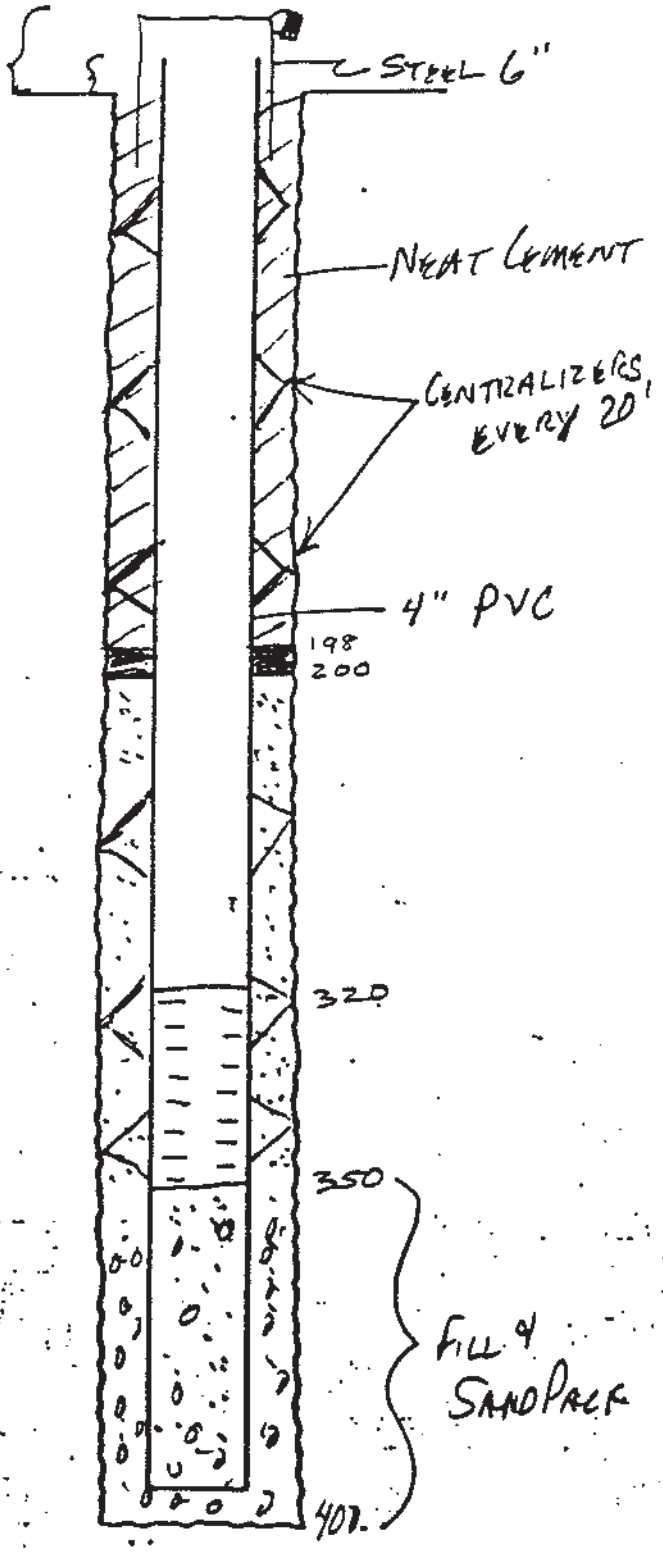
PIEZOMETER COMPLETION DIAGRAM

GW-3 / MALH 2278

DATE COMPLETED: 1-24-89 to 1-31-89
WEATHER: Cold, Hazy/Clear

PROJECT NAME/LOCATION: Atlas Grassy Mountain – Vale, Oregon
PROJECT # 219-8T-008
WELL LOCATION: Twn 26-20 & 26-21
PIEZOMETER NUMBER: (47-3) GW-3

PERMIT # _____
PROPERTY OWNER: BLM / Atlas
GEOLOGIST: K. Beiser / None
DRILLER: Duty Drilling / Dave Knarr & Bob D.
RIG TYPE & MODEL: Speedstar 15THH Air Rotary
AQUIFER: Bedrock – Grassy Mtn Fm?



COMPLETION SUMMARY

Total Well Depth 350
Stickup _____
Screen Type .020" PVC Sch 80 4" ID Flush Threaded
Screen 320 to 350
Top Seal:
Neat Cement from 0 to 198
Coarse Bentonite from 198 to 200
Gravel Pack from 200 to 400
Gravel Pack Material 8-12 Colo Silica
Bottom Seal:
None from _____ to _____
_____ from _____ to _____
Well Casing Diameter 6" steel + 4" PVC to 320
Well Casing Depth 6" steel to _____
Bit Diameter 12"
Drilled Depth 400'
Centralizers Every 20'
Protective Casing Yes – 6" steel
Logged – Y _____ N X
Type – SP ____ Res ____ Gamma ____
CAL ____ Por ____ Neutron ____
Remarks: Drilled to 400 ft w/ no measurable groundwater. Caving hole allowed PVC & sand pack to 350'. Washed down sand pack and poured 2 foot seal and trymmied neat cement. Boring past 250' & well installed unsupervised by Duty Drilling Co.

If abandonment, describe material and procedure in Item 12.

(3) TYPE OF WELL:
Rotary Air ☒ Driven ☐
Rotary Mud ☐ Dug ☐
Cable ☐ Bored ☐

(4) PROPOSED USE (check):
Domestic ☒ Industrial ☐ Municipal ☐
Irrigation ☐ Test Well ☐ Other ☐
Thermal: Withdrawal ☐ Reinjection ☐

(5) CASING INSTALLED:
Steel ☒ Plastic ☒
Threaded ☒ Welded ☒
10 " Diam. from +2 ft. to 99 ft. Gauge .250
6 " Diam. from +2 ft. to 245 ft. Gauge Sch. 80

LINER INSTALLED:
" Diam. from ft. to ft. Gauge

(6) PERFORATIONS:
Perforated? ☐ Yes ☐ No
Type of perforator used
Size of perforations in. by in.
perforations from ft. to ft.
perforations from ft. to ft.
perforations from ft. to ft.

(7) SCREENS:
Well screen installed? ☒ Yes ☐ No
Manufacturer's Name Aardvark
Type P.V.C. Sch. 80 Model No.
Diam. 6" Slot Size .020 Set from 380 ft. to 420 ft.
Diam. 325-355 Slot Size Set from 145 ft. to 255 ft.

(8) WELL TESTS:
Drawdown is amount water level is lowered below static level
Was a pump test made? ☐ Yes ☒ No If yes, by whom?
Yield: gal./min. with ft. drawdown after hrs.
" " " "
Air test 150 gal./min. with drill stem at 420 ft. 1 hrs.
Bailer test gal./min. with ft. drawdown after hrs.
Artesian flow g.p.m.
Temperature of water Depth artesian flow encountered ft.

(9) CONSTRUCTION:
Special standards: Yes ☐ No ☐
Well seal—Material used Bent. & Cement Grout
Well sealed from land surface to 18 ft.
Diameter of well bore to bottom of seal 12 1/4 in.
Diameter of well bore below seal 9 7/8 in.
Number of sacks of cement used in well seal 10 sacks
How was cement grout placed? Pressure Grout
Was pump installed? NO Type HP Depth ft.
Was a drive shoe used? ☒ Yes ☐ No Plugs Size: location ft.
Did any strata contain unusable water? ☐ Yes ☒ No
Type of Water? depth of strata
Method of sealing strata off
Was well gravel packed? ☒ Yes ☐ No Size of gravel: No. 8
Gravel placed from 100 ft. to 245 ft.

SPF WATER ENGINEERING

Executive Summary

Underground mine workings developed as part of the Grassy Mountain gold mine will intercept the regional water table and require dewatering. Pumping from wells outside the mine area to supply mine water demands will result in water table drawdown outside of the mine. In addition, the dewatering rate for the underground mine is an important process and water balance parameter. This report describes preliminary modeling efforts used to characterize pumping rates required for dewatering and impacts from groundwater pumping for mine water supply.

Theoretical groundwater inflow rates into the mine workings are on the order of 20 gpm to 100 gpm for sustained pumping, and up to 500 gpm for short-duration pumping, and reflect the wide span of aquifer parameters and model assumptions utilized for predictive analyses. Based on drilling observations (within the resource) and aquifer testing performed (outside the resource) to date, the higher-end range of potential inflow rates (associated with higher hydraulic conductivity) are unlikely to be encountered during mining activities and, if encountered, the associated high dewatering rates would be anticipated for relatively short durations (i.e., likely on the order of days or weeks). Due to the proposed underground mining approach, the entire groundwater table will not be intercepted at once. Rather, the exposure to groundwater is anticipated to be restricted to subsurface workings that encounter groundwater; where groundwater is present, such inflow can be managed or mitigated as the conditions arise.

The lower range of inflow rates represents longer-term predicted dewatering as steady-state conditions are approached and reflects lower overall permeability of the aquifer system over a greater area (and likely within the resource). The higher inflow rates reflect shorter-duration flow rates resulting from dewatering of larger zones with higher permeability and more water in storage that appear to be laterally discontinuous throughout the area based on borehole drilling and aquifer testing. Based on borehole drilling and well (aquifer) testing performed to date in the vicinity of the ore body, higher permeability areas are thought to more likely be encountered away from the silicified ore body (i.e., to the north of the ore deposit and in basin areas characterized by greater amounts of sediment as compared to silicified and/or competent bedrock deposits). Direct long-term testing of aquifer properties within the ore body has not been performed to date as verification, but extensive anecdotal evidence from mineral exploration drilling and the drilling on GMW18-34 supports the concept of low permeability materials within the near vicinity of the ore body.

These estimates are within the range of previous estimates prepared by ABC (1992) for an open pit mining scenario, on the order of 30 gpm to 3,000 gpm (described in Section 2.1). Variations in the estimates are attributed to aquifer property assignment, model assumptions and techniques, and time frames evaluated.

A modeling analysis to evaluate mine dewatering requirements has been prepared by Lorax Environmental Services, Ltd. (Lorax, 2021) subsequent to the one described in this report. The Lorax modeling analysis was based on refinements to the model presented herein to incorporate new information. The Lorax modeling analysis is summarized in the present report, and the results are generally consistent although Lorax predicts a narrower and somewhat lower range of potential dewatering rates.

Potential water level impacts caused by groundwater pumping for mine water supply (based on an estimated annual average demand of 320 gpm for ten years) are projected to range from approximately 0 to 12 feet of drawdown at the closest named spring (Lowe Spring) to the main production wells. The high end of impact is possible given the estimated aquifer properties if Lowe Spring is directly connected to the Grassy Mountain Formation aquifer from which the water is being produced, and assuming there are no compartmentalization affects caused by faulting. Drawdown effects are observed up to approximately 2 miles from the current highest producing well (PW-4), using a threshold of 0.5 feet of drawdown.

1. INTRODUCTION

Calico Resources USA Corp (Calico) proposes mining gold from patented and unpatented claims in the Grassy Mountain area. Developing the Grassy Mountain gold mine will require dewatering the mine and pumping groundwater to support mine operations.

. Calico seeks to dewater the active mining area in an interval between the elevations of approximately 3,500 and 3,100 feet, approximately 500 feet beneath ground surface.

Water is required to support numerous mine operations. The analyses presented in this report were based on an anticipated peak water-supply requirement is 400 gpm in the summer months and approximately 270 gpm during the remainder of the year. The annual average daily demand was projected to be about 320 gpm (0.71 cfs), or approximately 516 acre-feet per year . A map of the Proposed Grassy Mountain Mine including proposed and existing production wells and nearby springs is provide below as Figure 1.

The Feasibility Study recently issued (Ausenco, 2020) presents updated mining plans and water supply requirements. The mining plans presented in this new document are not much different from the earlier presentations on which the analyses presented herein are based, but the water supply requirements are much lower (i.e., on the order of 50 to 100 gpm annual average). Therefore, the results of this preliminary analysis should be viewed as a conservative (i.e., if the raw water demand is much higher than currently anticipated).

Calico seeks to characterize hydrogeology at the Grassy Mountain Project mine site to design dewatering and pumping systems. SPF Water Engineering, LLC (SPF), at Calico's request, has collected and compiled baseline hydrogeologic data (SPF 2021a) and developed a hydrogeologic conceptual model of the general mine area (SPF 2021b). This report describes the use of – and results from – analytical and numerical models to predict (1) dewatering requirements of the active mine-site area and (2) potential impacts of groundwater production on local groundwater levels.

Specific objectives of this modeling effort included the following:

1. Identify and use appropriate analytical methods to make a preliminary prediction of dewatering pumping rate requirements and production well pumping groundwater-level impacts.
2. Develop a numerical model to simulate groundwater flow in the vicinity of the Grassy Mountain mine site.
3. Simulate dewatering requirements and the effects of groundwater production on local springs using a range of hydraulic parameter values.
4. Conduct sensitivity simulations to help evaluate uncertainty associated with hydraulic-parameter choices.

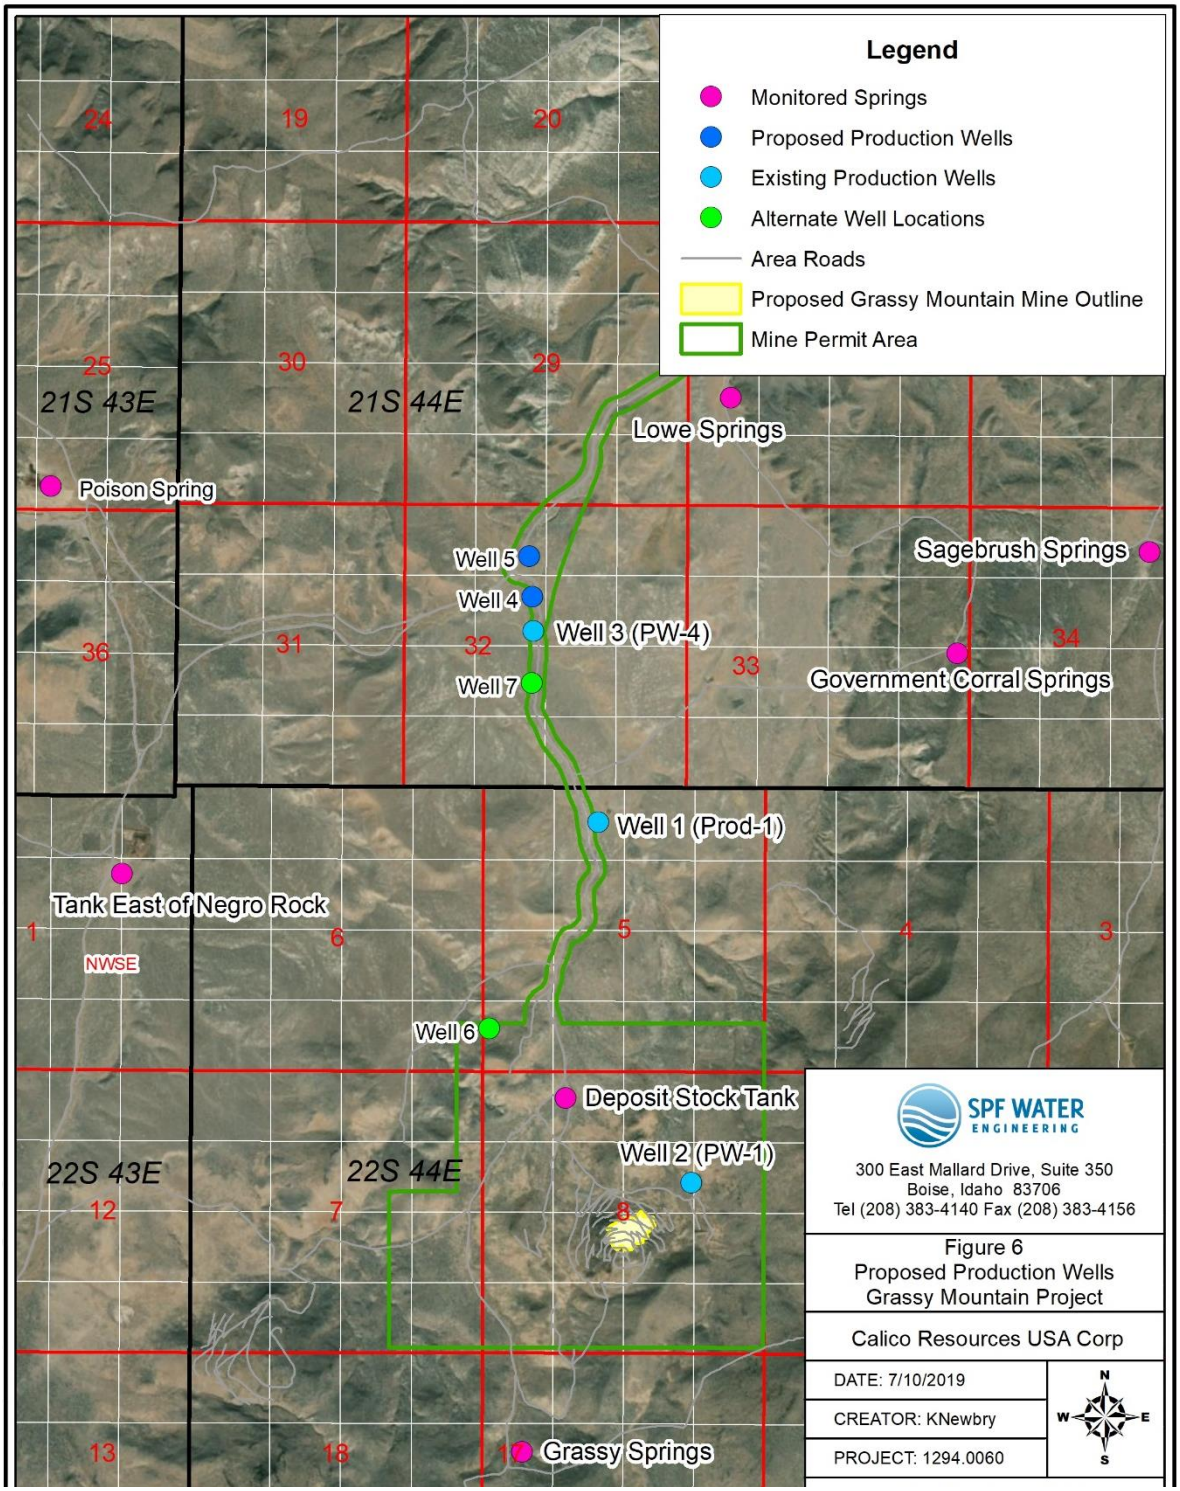

Figure 1. Proposed Grassy Mountain Mine and Production Wells

This modeling effort builds on a preceding conceptual model of groundwater flow (SPF 2021b) and supporting data sets. Other information used in developing the groundwater flow model includes the following:

- Monitoring Wells Completion Reports (SPF 2018a, SPF 2018b) – These documents present a summary of drilling, installation, and testing of three groundwater monitoring wells completed during 2017 and one additional upgradient monitoring well completed during 2018.

- Groundwater Resources Baseline Data Report (SPF 2021a) – This document presents a summary of groundwater baseline data collected since 2013, including groundwater levels, groundwater quality data from wells, spring discharge rates, and spring water quality data.

- Groundwater Characterization Report (SPF 2021b) – This document focuses on elements of the conceptual model. Specifically, the conceptual model report addresses the Technical Review Team Water Resources Subcommittee (TRT) request for a conceptual model and specific questions raised by the TRT about the conceptual model (Lynch, 2014).

- Well Field Design Report (SPF 2019) – This document provides a preliminary water supply evaluation, outlining projected water demands and proposed and existing water supply wells.

This preliminary numerical model simulating groundwater flow in the Grassy Mountain mine site area was built using existing hydrogeologic data. The existing hydrologic data are based on a limited number of measurements and observations. As such, the model and resulting projections has inherent uncertainty. Nonetheless, the model forms an initial foundation for incorporating future data, which, in turn, should reduce model uncertainty and improve model projections.

1.1. Report Organization

The remainder of this technical memorandum is organized as follows:

- Section 2 provides background information including a description of previous dewatering estimates, information sources, and modeling methods
- Section 3 summarizes the conceptual model
- Section 4 summarizes the analytical methods and results
- Section 5 summaries the numerical methods and results
- Section 6 provides an overall summary of this investigation
- Section 7 presents a summary of a supplemental report on dewatering
- Section 8 provides references

2. BACKGROUND

This section outlines previous dewatering estimates, describes information sources used for this modeling effort, and describes the general modeling methods.

2.1. Previous Dewatering Estimates

ABC (1992) prepared dewatering estimates for the Grassy Mountain resource to support an Environmental Impact Statement, assuming an open pit mine. The estimate was made using a two-dimensional numerical groundwater flow model. The model was used to (1) evaluate re-saturation time frame following mining operations and (2) predict the short- and long-duration effects of the mine project on the regional groundwater table and springs. The model simulated steady-state and transient groundwater flow in a single, unconfined aquifer, with groundwater flow influenced largely by topography.

The following model inputs were used in the ABC (1992) model construction:

- Uniform hydraulic conductivity
  - $2x10^{-3}$ cm/s (5.6 ft/d) in basin, low-elevation areas
  - $1.9x10^{-6}$ cm/s ($5x10^{-3}$ ft/d) in 'general' areas (interpreted to mean higher elevations)
  - $2x10^{-8}$ cm/s ($5.6x10^{-5}$ ft/d) for a simulated fault
  - $1x10^{-9}$ cm/s ($2.8x10^{-6}$ ft/d) for the resource area.
- Uniform recharge of 0.5 in/yr.
- Model thickness of 2,000 feet.
- Uniform specific storage $1x10^{-5}$ 1/L

The ABC model was calibrated to available groundwater-elevation observations to within +/- 40 feet of measured values. Scenarios were evaluated using the calibrated model to predict the amount of groundwater inflow based on the degree to which silicified rock ('shell') was removed from the vicinity of the open pit mine workings. The model predicted potential groundwater flow into the mine workings based on the particular scenario, ranging from:

- Essentially no predicted inflow, assuming that a rind or 'shell' of low permeability material on the order of $1x10^{-9}$ cm/s ($2.8x10^{-6}$ ft/d) remained around the entire perimeter in contact with material with an average permeability of $1.9x10^{-6}$ cm/s ($5x10^{-3}$ ft/d)
- 30 gpm (assuming that a partial shell of low permeability material remained around a portion of the mine working perimeter)
- 3,000 gpm (assuming an overall higher permeability of $1.9x10^{-4}$ cm/s or 0.5 ft/d under a 'partial shell' condition).

Calico Resources' exploration since 1992 has resulted in additional hydrogeologic data and a change in the mining strategy to an underground drift-and-fill operation. In this current

effort we have sought to use these new data (1) to project dewatering requirements and (2) evaluate pumping capacity and associated impacts.

2.2. Methods

A combination of analytical and numerical modeling approaches was used in this current effort to project dewatering and production rates and potential aquifer drawdown impacts. The dewatering estimates were intended to bracket potential groundwater inflow rates based on the expected range in aquifer properties.

2.2.1. Analytical Methods

Two two-dimensional analytical methods were used to evaluate steady-state[1] and transient[2] dewatering effects:

- The steady-state two-dimensional method (Marinelli and Niccoli, 2000) incorporated both horizontal shallow flow and vertical, deeper flow contributions into the resource area. This method uses two steady-state analytical solutions useful for predicting the groundwater inflow to a mine pit excavated below the water table. Although the proposed mining method is drift-and-fill, calculating the inflow to the entire proposed Grassy Mountain Mine area provides a conservative dewatering estimate. The total inflow rate was the sum of the estimated flow rate from both the horizontal and vertical flow components.

- The transient method used the Theis equation (Theis, 1935) to simulate the effects of pumping on drawdown over time with distance from a pumping well. Assumptions inherent to the use of the non-equilibrium Theis equation are that the aquifer is homogeneous and isotropic, uniform in thickness and areal extent, and receives no recharge; the pumping well penetrates the full aquifer thickness; water removed by discharge is removed instantaneously; the pumping well is 100% efficient; laminar flow exists throughout the aquifer; and the water table or potentiometric surface has no slope. Some of these assumptions are rarely completely satisfied under field conditions, but this method is commonly used for evaluating pumping (or dewatering) questions. In this case, some of the assumptions are clearly not met (e.g., the aquifer is not homogeneous and isotropic, uniform in thickness and areal extent) but nonetheless use of the method gives insight into possible dewatering rates.

2.2.2. Numerical Methods

Numerical groundwater flow modeling under steady state and transient conditions (see Section 5) was performed using the MODFLOW code (Harbaugh, et. al., 2000). Developed

---

[1] Steady-state (or equilibrium) hydraulic conditions are those in which the magnitude and direction of groundwater flow is constant in time.

[2] Transient conditions are those in which the magnitude and direction of groundwater flow may vary in time.

by the U.S. Geological Survey (USGS), MODFLOW is a finite difference code capable of simulating three-dimensional groundwater flow. The code allows for representation of greater complexity than the analytical methods described above, and is commonly used for simulating groundwater flow.

In general, dewatering was simulated in the MODFLOW model by assigning pumping wells along the perimeter and inside the proposed Grassy Mountain Mine, and the groundwater elevation during pumping was compared to the target dewatering elevation. Pumping wells were assigned in the analytical and numerical models to simulate the overall magnitude of aggregate dewatering rates. In reality, dewatering of the underground workings may be performed by booster pumps, sumps, or dewatering galleries, as needed. A limited sensitivity analysis was performed to evaluate the effects of hydraulic conductivity, storativity, and recharge on the results.

2.3. Information Sources

Information used in in this analysis included the following:

- Borehole/well completion and lithologic logs;
- Groundwater levels measured in wells and VWPs;
- Potentiometric surface maps;
- Aquifer pumping tests;
- Recharge/discharge estimates;
- Aerial photographs, topographic maps, surface geologic maps, and geologic cross-sections;
- Aquifer hydraulic properties for lithologic units determined from test pumping and published values for similar materials;
- Water quality data collected from wells and springs; and
- Available published reports.

This information can be found in the baseline or characterization reports.

3. CONCEPTUAL MODEL

This section describes a conceptual understanding of groundwater flow in the vicinity of the proposed mine site. The conceptual understanding, or conceptual model, represents the basis for analytical and numerical modeling. A more detailed conceptual model is outlined in the Groundwater Characterization Report (SPF 2021b).

3.1. Hydrogeology

Groundwater is present in unconsolidated or weakly-consolidated sandstone and conglomerate units and interbedded sediments associated with the Grassy Mountain Formation. Water-bearing zones appear to be somewhat compartmentalized, reflecting faulting, sedimentary facies changes, and silicification. Primary flow occurs in fractures, faults, unconsolidated (or semi-consolidated) materials, and zones or pockets of less-silicified rocks. Material properties such as degree of consolidation, degree of silicification, fracture characteristics, and fault characteristics influence hydraulic conductivity, which in turn influences the rate and magnitude of groundwater flow. Individual aquifer zones are highly heterogeneous as a result of variations in aquifer-material characteristics, lateral and vertical unit pinch-outs, and numerous identified faults/fault zones.

3.2. Recharge and Discharge

Recharge consists of infiltration from precipitation. Annual recharge to groundwater in the vicinity of Grassy Mountain has been estimated in the range of 0.25 to 1 inch based on climatic and topographic conditions (ABC, 1992). Discharge occurs to springs and surface channels at lower elevations. Regional groundwater flow is to the north towards the Malheur River.

Within the Grassy Mountain vicinity, numerous individual springs (some ephemeral) have been identified and monitored for flow and water quality during investigations for baseline and background characterization purposes. The majority of springs have measured flow rates of less than one gpm, although the flow rate in several springs has been measured over 1 gpm. The annual average discharge from monitored springs located on the north side of the Grassy Mountain hydrologic divide is on the order of approximately 30 gpm based on flow measurements collected between 2013 and 2017. There are additional springs farther downgradient that were not monitored for flow that could also serve as regional groundwater discharge points. The total aggregate visible groundwater discharge is an indicator of the low annual recharge rate. For example, if the watershed contributing to spring flow is 25 square miles, the visible discharge rate of 30 gpm reflects an average recharge rate of approximately 0.04 inches per year.

Flow directions are generally perpendicular to topographic contours. The groundwater flow direction is predominantly to the northwest and more or less continuous in the vicinity of the proposed Grassy Mountain Mine. The horizontal hydraulic gradient is relatively high in upland areas, reflecting the steep topography, recharge areas, and predominantly low permeability of subsurface deposits. The gradient lessens in lower elevation areas coinciding with flatter topography and areas of groundwater discharge.

Short term pumping rates from wells within the immediate vicinity of the proposed Grassy Mountain Mine range from less than a few gallons per minute (gpm) up to a few tens of gallons per minute. Pumping rates further away from the proposed Grassy Mountain Mine are higher (up to 145 gpm in PW-4). Apparent negative boundaries, reflecting the

compartmentalized nature of geologic materials, were apparent in most wells. These boundaries limit sustainable pumping rates from wells.

3.3. Single Aquifer System

Faults and fractures, lithologic facies changes, and silicification of formation sediments are responsible for substantial heterogeneity on a local scale. However, the aquifer appears to be somewhat more homogeneous (i.e., homogeneously heterogeneous) on a regional scale.

There is insufficient evidence to identify discrete zones within the project area that are isolated or partially isolated from other zones. In general, assignment of discrete zones is based on several criteria, with the designation being somewhat subjective and relative as a function of scale:

- Physical separation of higher permeable deposits (aquifers) by lower permeable deposits (aquitards)
- Hydraulic communication (i.e., similar groundwater elevation trends)
- Similar lithologic, water quality and geochemical characteristics.

There are clearly heterogeneous, compartmentalized, discrete water-bearing zones in the general mine vicinity (JMM 1991; ABC 1992; SPF 2021b). Water-bearing zones may be laterally discontinuous, have lower permeability than surrounding areas (such as would be the case with local clay and siltstone, competent bedrock, and silicified deposits), and have joints or structural barriers (e.g. faults) to groundwater flow (SPF 2021b). Aquifer material, water levels, and flow characteristics vary spatially and by depth.

The concept of a single aquifer system is proposed, and is consistent with previous investigations. This single aquifer system contains discrete water-bearing zones that are laterally discontinuous and partially separated by structural barriers to groundwater flow.

The presence of a deeper, regional aquifer has been contemplated based on the measured groundwater elevations over time in Well 59762 (approximately 3,100 feet above mean sea level, amsl), compared to other nearby wells with groundwater elevations of 3,200 feet amsl or higher (SPF 2021b). Well 59762 was completed to approximately 700 feet bgs, deeper than other wells installed in the resource vicinity. In terms of elevation, however, other, hydraulically downgradient wells are actually screened over a comparable or lower elevation (i.e., GW-4, PW-4, Prod-1, and GW-6) but exhibit higher groundwater elevations. Since well 59762 was installed, one additional deep well (GMW17-32) was installed downgradient of the deposit area in 2017, and several deep vibrating wire piezometers (VWPs) have been installed directly within the highly silicified deposit in the location of the proposed Grassy Mountain Mine (SPF 2017). Those installations have deeper groundwater elevations similar to Well 59762 (i.e., 3,000 to 3,100 feet amsl range), supporting the concept of a deeper zone within the aquifer system, at least in the vicinity of the silicified deposit.

The presence and quantity of groundwater within deposit area of the proposed Grassy Mountain Mine can be described based on water reported during exploratory drilling, monitoring well construction and testing, and VWP water level data.

Figure 2 shows the proposed Grassy Mountain Mine, along with selected drill holes, monitoring wells, and piezometers. The holes with reported water are noted, with depth, elevation, and quantity of water as observed by the well driller. The quantity of water refers to flow of water air-lifted from the hole during drilling; there is not an indication of duration of flow in the driller notes. Within the footprint of the deposit area, most of the drill holes did not encounter any water (as shown on Figure 2). Of the holes that did encounter water, flows were less than 25 gpm and often from a depth of more than 800 feet (below an elevation of 3,000 feet). When drill holes encountered water outside the deposit area, higher flows in excess of 50 gpm were occasionally noted, generally east of the proposed Grassy Mountain Mine. This area is typically less silicified. Higher well yields are likely associated with less silicified materials. It is also possible that the Badger and Schweizer faults act as barriers to groundwater flow on the east and south sides of the proposed Grassy Mountain Mine.

Figure 2 also includes the monitoring wells in the immediate vicinity of the deposit area, with elevation of the screened interval and short-term production noted. The deeper wells screened below an elevation of about 3,200 feet are dry or poor producers. GMW17-33 (screen interval 3,466-3,366 feet) is a moderately productive well; the well was test pumped at an average rate of 28 gpm for about 2 days before a negative boundary caused the pumping water level to reach the pump. Additional information is provided in the Groundwater Characterization Report (SPF 2021b).

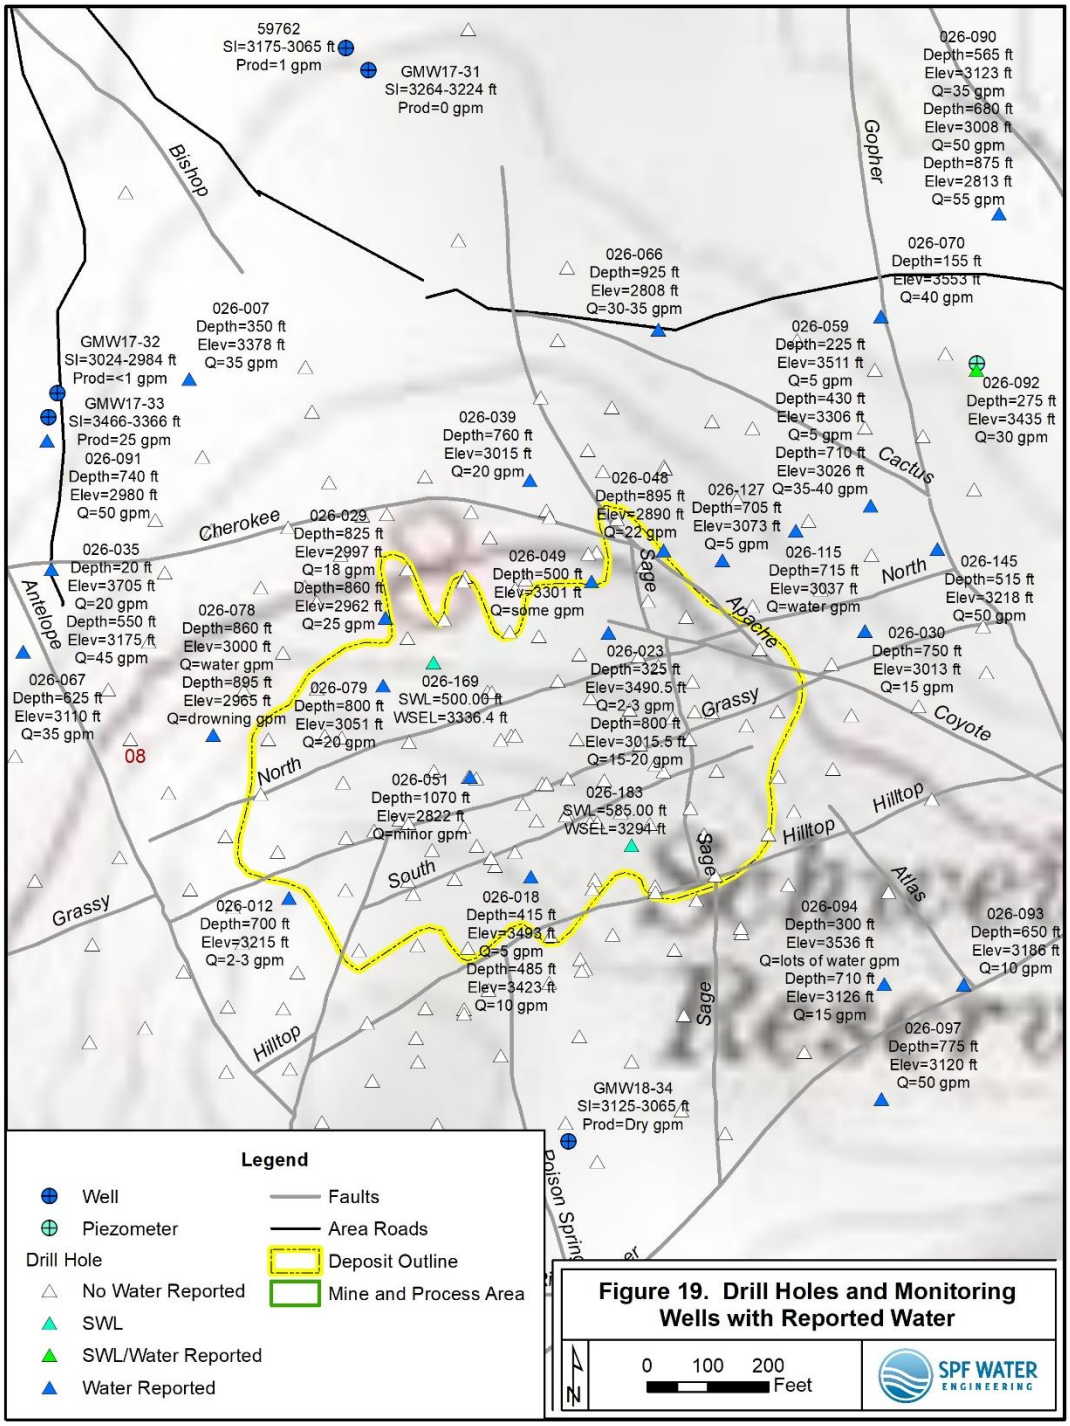

Figure 2. Drill holes and monitoring wells with reported water

Installation of an upgradient deep monitoring well in 2018 (GMW18-34) helps define the extent of the silicification of the aquifer on the upgradient side of the proposed Grassy Mountain Mine. This monitoring well was drilled approximately 40 feet into the underlying Kern Basin Tuff to 950 feet bgs (3,003 feet amsl) with no indication of available groundwater and was screened from 830 to 890 feet bgs (3,127 to 3,067 feet amsl) with no static water level measured to date. The current VWP installations, combined with deep wells, indicate the potential exists to encounter groundwater within the resource area both above and below the target dewatering elevation of approximately 3,100 feet amsl, with lower static groundwater elevations found in water-bearing zones at depths of more than approximately 500 feet below ground surface.

As previously discussed in the Groundwater Characterization Report (SPF 2021b), pervasive silicification of sediments also has a major impact on groundwater conditions within the proposed Grassy Mountain Mine. It is likely that the combination of silicification, faulting, and the interbedded low-permeability sediments serve to impede groundwater flow into and within the proposed Grassy Mountain Mine. Even with the Schweizer and Badger faults apparently acting as a lower permeable barriers in the sandstone and arkose, it is possible for faulting to be the cause of increased permeability in the underlying tuff if localized silicification caused the tuff to become more brittle, thereby increasing fracturing during faulting. With significantly more faulting near the proposed Grassy Mountain Mine than the rest on the study area, in combination with localized silicified, brittle tuff, it is possible that silicified sediments within the Mine footprint are draining into the underlying tuff. In other words, the fractured tuff may have a high enough hydraulic conductivity to drain the small amount of water that can flow into the overlying compartmentalized sections of silicified sediments from upgradient areas.

The overall direction of groundwater flow and hydraulic gradients are similar for shallow and deeper wells; groundwater levels in shallow and deeper wells both suggest a strong topographic influence. The geochemistry in both shallow and deep wells is similar (i.e., without a clear distinction based strictly on vertical/depth trends). Thus, while there may be distinctions between shallow and deeper aquifer zones, there appears to be a coherent regional flow system in the general mine area.

There are insufficient data to fully describe – or simulate – the complex, heterogeneous nature of aquifer materials within the study area. Available data do not allow a highly complex depiction of the aquifer system. Thus, the resolution of the models used in this investigation that simulate this system are intended to capture aggregate, overall behavior of groundwater flow and hydraulic gradients and not necessarily the exact conditions at a single location (i.e., well or piezometer).

4. ANALYTICAL APPROACH

Two analytical approaches were used to evaluate potential dewatering needs; one analytical solution was used to project production-well drawdown impacts. This section describes these approaches and corresponding results.

4.1. Dewatering

Inflows under steady-state conditions (see Section 4.1.1) were projected using analytical equations by Marinelli and Niccoli (2000); inflows under transient conditions were evaluated using the Theis equation (Section 4.1.2).

- For the steady-state analysis, potential groundwater inflow into the proposed mine workings were estimated from (1) shallow aquifer zones present at the same elevation as mine workings and (2) a deeper zone within the aquifer beneath the mine workings. The rate obtained from the steady-state approach reflects equilibrium, long-duration dewatering conditions and does not necessarily reflect dewatering estimates under a short-duration. Initially, higher pumping rates are anticipated due to higher groundwater inflow during the early stages of dewatering. Dewatering requirements are expected to lessen over time as dewatering takes place in the surrounding aquifer until steady-state conditions are ultimately reached.

- The transient analysis, outlined in Section 4.1.2, involved performing Theis drawdown calculations (Theis, 1935) to evaluate potential short-duration pumping requirements. This method calculates drawdown effects with distance from the pumping location over time. The assumed pumping center is in the middle of the resource area, and theoretical drawdown is calculated at a distance that coincides with the edge of the resource area (i.e., approximately 0.1 mile from the center of the proposed Grassy Mountain Mine).

Both methods require simplifying assumptions. For example, the analytical methods used a single value to represent aquifer properties (i.e., transmissivity and storativity) at a fixed, constant pumping rate. In reality, the aquifers around and beneath the resource area are complex, heterogeneous and, variable. Nonetheless these methods provide insight into possible dewatering rates and pumping impacts.

4.1.1. Steady State Analysis

4.1.1.1. Equations

The Marinelli and Niccoli (2000) equation used to evaluate potential inflow rates into the mine workings consists of the following:

$$(1)\ h_o = \sqrt{h_p^2 + \frac{W}{K_{h1}}\left[r_o^2 \ln\left(\frac{r_o}{r_p}\right) - \frac{(r_o^2 - r_p^2)}{2}\right]}$$

where:

h_0 = initial (pre-mining) saturated thickness above the base of Zone1 (shallow aquifer)

h_p = saturated thickness above the base of Zone 1 at the effective radius (outer extent) for the mine workings

W = recharge to the water table

K_{h1} = horizontal hydraulic conductivity

r_0 = maximum radius of influence (calculated value)

r_p = effective radius of the mine workings.

This solution accounts for uniform recharge applied at the water table with a saturated aquifer of uniform hydraulic conductivity. Groundwater flow is horizontal (assuming an initial relatively flat hydraulic gradient exists before dewatering takes place).

The radius of influence (r_0) from groundwater inflow along the mine walls is determined by iteration using the above equation, using on the radius of the mine workings, initial saturated thickness of the aquifer, and target drawdown extent for Zone 1 (shallow aquifer) at the fully dewatered state. With r_0 from the above equation, the rate of inflow can then be determined from the following equation:

$$(2)\ Q_1 = W\,\pi\,(r_o^2 - r_p^2)$$

where:

Q1 = inflow rate into the walls of the mine workings

W = recharge

r_0 = maximum radius of influence

r_p = effective radius of the mine workings.

In this exercise we assumed a saturated aquifer thickness of 580 feet based on a groundwater table elevation of 3,680 feet amsl near the upgradient end of the proposed Grassy Mountain Mine and a target dewatering elevation of approximately 3,100 feet amsl,

with 100% dewatering. This value for saturated thickness represents an assumed maximum thickness, as the actual aquifer thickness contributing to groundwater flow is likely less. Based on monitoring of VWP sensors installed during 2017 within the proposed Grassy Mountain Mine, groundwater was encountered at elevations ranging from approximately 3,075 to 3,400 amsl (SPF, 2017). VWP units were installed at five, angled borehole locations, with three VWP sensors installed per borehole. Installations were primarily located on the eastern side of the proposed Grassy Mountain Mine. Information on the occurrence of groundwater reflects these locations and does not necessarily conditions in other areas of the proposed Grassy Mountain Mine.

A second set of equations represents vertically upward flow from the deep aquifer beneath the mine through the bottom of the mine workings (Zone 2), should this condition be encountered. The combined inflow from Zone 1 and Zone 2 represents the total predicted inflow into the mine workings.

The following equation solves for the predicted inflow into the mine workings through the bottom of the mine (Zone 2):

$$Q_2 = 4\, r_p \left(\frac{K_{h2}}{m_2}\right) (h_o - d)$$

$$m_2 = \sqrt{\frac{K_{h2}}{K_{v2}}}$$

where:

Q_2 = inflow rate into the bottom of the mine workings

r_p = effective radius of the mine workings

K_{h2} = horizontal hydraulic conductivity within Zone 2

K_{v2} = vertical hydraulic conductivity within Zone 2

m_2 = anisotropy parameter (to account for variations in horizontal and vertical hydraulic conductivity)

h_0 = initial (pre-mining) saturated thickness above the base of Zone1 (shallow aquifer)

d = depth of the water in the mine workings (assumed to be negligible during full dewatering).

These equations were developed for estimating inflow into an open pit of certain dimensions.[3] Although the proposed mining operations for Grassy Mountain are based on subsurface mining techniques and not an open pit scenario, the use of these equations represents aggregate, potential flow to the mine. Other techniques for estimating potential dewatering were evaluated to provide a multiple lines-of-evidence approach, particularly given the stated limitations for the steady-state method (i.e., relatively flat initial water table). In reality, the horizontal hydraulic gradient throughout the proposed target area is relatively steep in some areas which may not accurately predict inflow rates.

4.1.1.2. Scenarios and Results

Three general scenarios (i.e., 1, 2, and 3) were used to evaluate potential steady-state inflows. These scenarios are distinguished by low, intermediate, and high hydraulic conductivity values (ranging from 10^{-6} cm/s to 10^{-4} cm/s, or 0.003 ft/d to 0.3 ft/d) for the shallow aquifer zone, and low hydraulic conductivity (10^{-6} cm/s, or 0.003 ft/d) for the deep zone (Table 1). These values reflect the typical measured range in transmissivity (and hydraulic conductivity) from historical and recent pumping tests. Recharge rates ranging from 1 in/yr to 0.07 in/yr were used while holding all other input parameters constant. Based on previous modeling efforts (ABC 1992) and observed discharge from area springs, recharge values of 0.5 in/year or less are the most likely conditions.. Vertical isotropy was assumed in all cases (although, in reality, this parameter likely varies one to two orders in magnitude). Variations in each scenario included lowering the recharge rate to 1 in/yr and 0.07 in/yr while holding all other input parameters constant.

Several of the same inputs used for Zone 1 estimates are also used for Zone 2. The initial water table for Zone 2 is assumed to be the same as Zone 1.

[3] Several assumptions apply to the equations including a decrease in saturated aquifer thickness as the water table is lowered during dewatering, predominant inflow through upward flow components as opposed to lateral seepage effects through the walls of the mined areas, semi-infinite aquifer conditions beneath the mine with no impermeable boundary effects, steady-state flow conditions, and no flow between Zones 1 and 2.

Table 1. Steady-state estimated groundwater inflow rates

Scenario	Description	Shallow Hydraulic Conductivity, K (Zone 1)	Deep Hydraulic Conductivity, K (Zone 2)	Recharge (in/yr)	Estimated Discharge (gpm)		
					Shallow (Zone 1)	Deep (Zone 2)	Combined Zones
1	Low K (shallow); High Rch	$1x10^{-6}$ cm/s (0.003 ft/d)	$1x10^{-6}$ cm/s (0.003 ft/d)	1	24	15	39
1a	Low K (shallow); High Rch			0.5	12	15	27
1b	Low K (shallow); Mid Rch			0.25	10	15	25
1c	Low K (shallow); Low Rch			0.07	8	15	23
2	Mid K (shallow); High Rch	$1x10^{-5}$ cm/s (0.03 ft/d)	$1x10^{-6}$ cm/s (0.003 ft/d)	1	146	15	161
2a	Mid K (shallow); High Rch			0.5	73	15	88
2b	Mid K (shallow); Mid Rch			0.25	64	15	80
2c	Low K (shallow); Low Rch			0.07	53	15	68
3	High K (shallow); High Rch	$1x10^{-4}$ cm/s (0.3 ft/d)	$1x10^{-6}$ cm/s (0.003 ft/d)	1	1,002	15	1017
3a	High K (shallow); High Rch			0.5	501	15	516
3b	High K (shallow); Mid Rch			0.25	457	15	472
3c	High K (shallow); Low Rch			0.07	394	15	409

The results suggest half an order of magnitude variation in the inflow rate between each of the three scenarios when using a recharge rate of 0.5 in/yr or less (i.e., approximately 27 gpm for Scenario 1; 88 gpm for Scenario 2; and 516 gpm for Scenario 3). Lowering the recharge rate did not significantly change the predicted inflow. Supporting equations for Zones 1 and 2 and calculations for each scenario are provided in Appendix A. In each scenario, using a recharge rate of 1 in/yr doubles the highest estimated inflow value.

It has been previously stated that the best estimates for recharge rates are between 0.25 and 1 in/year based on climate and topographic conditions (ABC, 1992). The model from the same report used an assigned recharge rate of 0.5 in/year and monitored spring flow from 2013 to 2017 supports a lower annual recharge rate as discussed in Section 3.2.

4.1.2. Transient Analysis

The Theis analytical method (Theis, 1935) yields a theoretical projection of potential drawdown effects associated with pumping to achieve mine dewatering over a period of time. In contrast, the steady state method described above does not account for variations in drawdown over time. Thus, the Theis method was used to evaluate the amount of time that may be necessary to dewater the mine workings to the target elevation of approximately 3,100 feet.

For this analysis, it was assumed that a single pumping well placed at the center of the mine workings could be used to evaluate the predicted drawdown at a distance from the pumping well that coincided with the perimeter of the mine workings. In reality, dewatering of the underground workings may utilize booster pumps or sumps placed as needed as opposed

to a vertical well. Based on an approximate radius of 450 feet (roughly 0.1 mile), the pumping rate was adjusted to achieve the maximum projected drawdown of roughly 600 feet (i.e., 3,700 feet elevation minus 3,100 feet elevation) at 0.1 mile.

For scenario 2a, the most likely scenario (mid T, mid S), we assumed an aquifer transmissivity of 100 gallons per foot per day (gpd/ft), which is within the typical range based on aquifer testing (i.e., on the order of a few 10s to 250 gpd/ft, excluding PW-4 outlier), and storativity of 0.005 (upper range for confined conditions). Assuming a saturated aquifer thickness of 200 feet, the 100 gpd/ft transmissivity is equivalent to a hydraulic conductivity of 0.07 ft/day (2 x 10^{-5} cm/s) and is within the range of estimated values derived from pumping tests conducted within the vicinity of the resource area. The actual aquifer thickness varies across the resource area; however, this assumed value provides an upper-end of expected drawdown. The storativity of 0.005 represents the upper range for confined aquifers (0.005 to 0.00005) based on literature reported values (Freeze and Cherry, 1979).

Based on the Theis analysis, the predicted pumping rate needed to achieve the total drawdown in the pumping well was estimated to be roughly 250 gpm for one year. Actual drawdown effects will vary depending on actual aquifer conditions encountered within the resource area and the well efficiency. The predicted drawdown after one year of continuous pumping was approximately 600 feet at 0.1 mile from the pumping location in the center of the mine workings (Figure 3).

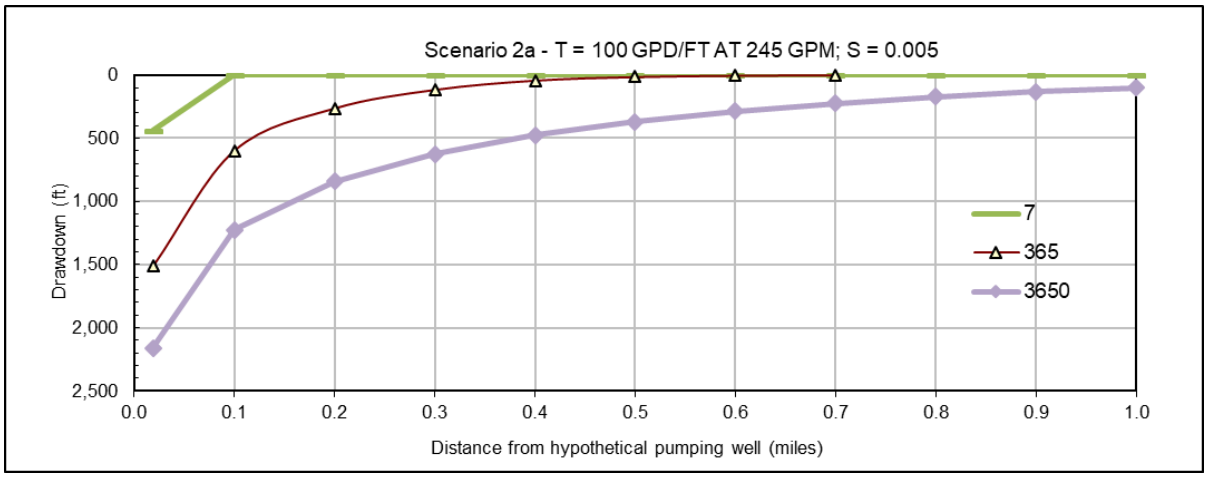

Figure 3. Theis predicted drawdown (100 gpd/ft and 250 gpm scenario for 7 days, 365 days, and 3650 days).

In reality, a single well will not sustain a pumping rate of 250 gpm due to excessive drawdown effects and unsustainable yield at that rate; several wells and/or pumps within the

mine workings will be required to dewater the mine area. However, this simulation helps describe an order-of-magnitude pumping requirement to achieve the desired amount of dewatering.

Multiple scenarios were used to examine different hydraulic conductivity and storativity assumptions (aquifer thickness was assumed to remain the same). Hydraulic conductivity values of 0.003 ft/d, 0.07 ft/d, and 0.3 ft/d were assumed for Scenarios 1, 2, and 3, respectively. The storativity values ranged from a low confined aquifer value of 0.00005, with the mid-range semi-confined value of 0.005, and a high value of 0.05 indicative of unconfined conditions. The pumping rate was adjusted in each case (ranging from 6 gpm to 1,600 gpm) to produce 600 feet of drawdown across the resource area after one year of pumping. The 0.003 ft/day and 400 gpm scenario is not feasible because a 400-gpm pumping rate could not be developed or sustained without many thousands of feet of drawdown at the center of the cone of depression.

Lowering the storativity value to the lower-end range of 0.00005, had the effect of lowering the pumping rate necessary to achieve the target drawdown. Raising the storativity value to the higher-end range of 0.05, had the effect of increasing the pumping rate necessary to achieve the target drawdown, and in one case (low transmissivity), made it impossible with a single well. Supporting calculations for the Theis drawdown estimates are provided in Appendix B. Results of the multiple scenarios are provided in Table 2 below.

Table 2. Theis analytical model predicted dewatering flows

Scenario	Description	Transmissivity, T (gpd/ft)	Storativity, S (dimensionless)	Approximate Flow Required to Dewater 500 Feet at a Distance of 0.1 Mile After One Year (gpm)
1	Low T; Low S	4	0.00005	6
1a	Low T; Mid S	4	0.005	380
1b	Low T; High S	4	0.05	>1,000,000
2	Mid T; Low S	100	0.00005	80
2a	Mid T; Mid S	100	0.005	245
2b	Mid T; High S	100	0.05	1,450
3	High T; Low S	400	0.00005	260
3a	High T; Mid S	400	0.005	605
3b	High T; High S	400	0.05	1,600

4.2. Production Well Drawdown Impacts

The Theis method used for estimating dewatering rates was also used to project the aquifer impacts due to production well pumping over the life of the mine. The same limitations and assumptions described above for mine dewatering also apply to the estimation of aquifer impacts from production water pumping.

In this analysis we evaluated impacts of pumping 320 gpm from a single well, although current estimates of the groundwater demand by the mine are much lower (i.e., on the order of 50 gpm). In reality, several production wells are planned within an approximate 0.27-mile radius of PW-4. Furthermore, wells Prod-1, PW-1 and possibly Well 6, which are located approximately 0.71 miles, 2.06 miles, and 1.44 miles south of PW-4, respectively, could also be available for production.

A near well aquifer transmissivity ranging from 1,700 gpd/ft (after negative boundary) to 3,800 gpd/ft (before negative boundary) and storativity of 7.0×10^{-5} were calculated from an aquifer test performed at PW-4 in 1989 (SPF 2021b). A range of transmissivities and storativities spanning these calculated values were used to analytically predict the drawdown from production well pumping.

The predicted drawdown from production well pumping calculated by the Theis analytical model is presented as Table 3 below. As mentioned before, this method does not account for recharge. It is used to show the maximum possible extent of the cone of depression from the production wells pumping after ten years. Supporting data and plots for each scenario are also provided in Appendix B.

Table 3. Theis analytical model predicted production well drawdown

Scenario	Description	Transmissivity, T	Storativity, S	Calculated Drawdown After Ten Years (feet)		
				One Mile	Four Miles	Seven Miles
1	Low T; Low S	1,500 gpd/ft	0.00005	172.92	105.31	78.33
1a	Low T; Mid S		0.0005	116.74	50.66	26.86
1b	Low T; High S		0.005	61.48	8.14	0.60
2	Mid T; Low S	4,000 gpd/ft	0.00005	73.84	48.44	38.23

2b	Mid T; High S		0.005	31.78	8.64	2.49
3	High T; Low S	10,000 gpd/ft	0.00005	32.89	22.73	18.63
3a	High T; Mid S		0.0005	24.45	14.32	10.31
3b	High T; High S		0.005	16.03	6.25	2.91

5. NUMERICAL METHODS

The analytical methods used to project dewatering requirements and possible impacts from pumping (see Section 4) are simplified solutions for analyzing a complex problem. A numerical model was constructed to further evaluate potential dewatering requirements and groundwater-production impact. A numerical model is also a simplified representation of a complex system, but allows more simulation flexibility (such as including a sloping aquifer and multiple pumping wells). This section describes model construction, parameter values, calibration results, sensitivity analysis, and the results from an additional dewatering scenario.

5.1. Code Selection

The USGS code MODFLOW 2000 (Harbaugh, A.W, et. al., 2000) was used for performing numerical groundwater flow modeling and dewatering projections. MODFLOW uses a modular finite-difference approach for simulating groundwater flow in three dimensions. MODFLOW is considered as the industry standard and is widely accepted within the hydrologic community for dewatering applications.

Groundwater Vistas (GV) was used to construct and execute MODFLOW simulations. GV was developed by Environmental Simulations Incorporated as a graphical user interface for pre- and post-processing of MODFLOW files (ESI, 2011). GV supports geographic information system (GIS) files for data visualization.

5.2. Spatial and Temporal Discretization

The following summarizes the spatial and temporal setup in the model.

The model extent was approximately 10 miles by 10 miles, centered on the proposed Grassy Mountain Mine. The southern model boundary extended to portions of Owyhee Reservoir and the Owyhee River. The northern boundary extended north of Poison Creek. The eastern and western boundaries were set to comparable distances from the proposed resource and did not necessarily coincide with physical features. This domain was selected to minimize the potential effects of setting the boundary and assigned conditions too close to the proposed resource and thereby influencing the model's prediction of groundwater levels and drawdown from pumping in the resource area.

The model grid was comprised of 264 rows and 264 columns with uniform grid cell dimensions of 200 feet by 200 feet. The model was rotated 45 degrees counterclockwise to approximate the general, predominant direction of groundwater flow to the northwest in the vicinity of Grassy Mountain and the resource area. This rotation effectively allows groundwater flow to be simulated in three dimensions.

The coordinate system for the model was NAD 1983, State Plane Oregon, South, FIPS 3602 in feet with Lambert Conformal Conic projection.

The model consisted of three layers (layer 1, layer 2, and layer 3) defined to reflect topographic influences on groundwater flow:

- Layer 1 was typically 100 feet in thickness and formed the uppermost layer defined by the topographic surface. This layer represents surficial and shallow lithology and contains boundary conditions for select surface water features represented in the model (as drain and river cells) described in the next section. Layer 1 was simulated as an unconfined layer condition, where transmissivity was allowed to vary.

  The surface of the model was created from a digital elevation model (DEM) of topography with 30-meter (approximately 100 foot) resolution (USGS, 2017)[4]. The USGS created the DEM from surface topography maps converted into digital format. Once the DEM was imported into the model, the top elevation of Layer 1 ranged from approximately 2,115 feet to 4,733 feet amsl.

- Layer 2 was the middle layer, intended to represent the shallow aquifer system and has a non-uniform thickness, ranging from less than 100 feet in lower-topography areas to nearly 1,000 feet at the center of the model. This layer contains most of the monitoring wells used as calibration targets for the model. This layer was assigned a uniform bottom elevation of 3,100 feet in the resource area as the target depth for dewatering. Pumping simulations were evaluated by comparing the predicted groundwater elevation to the 3,100-foot elevation level to assess magnitude of dewatering needs to achieve 100 percent dewatering in the resource area. Layer 2 was simulated as a confined condition.

- Layer 3 was the lowest layer in the model, with non-uniform thickness and an assigned uniform model base of 2,000 feet amsl. The bottom of this layer is implicitly a no-flow boundary. Layer 3 was simulated as a confined condition.

Numerical model simulations were performed under steady-state and transient conditions. The steady-state system reflects the groundwater flow regime once equilibrium has been established and does not account for changes in groundwater levels over time, which may occur on the order of decades or longer.

5.3. Initial and Boundary Conditions

Initial and boundary conditions represented in the model are intended to reflect actual, hydraulic boundaries to the extent possible based on available information. Boundary

[4] The DEM was downloaded from the website: https://earthexplorer.usgs.gov/. The data source for the DEM is the Advanced Spaceborne Thermal Emission and Reflection Radiometer (ASTER) Global Digital Elevation Model.

conditions assigned in the model included constant head, river, drain, and no-flow boundaries (Figure 4).

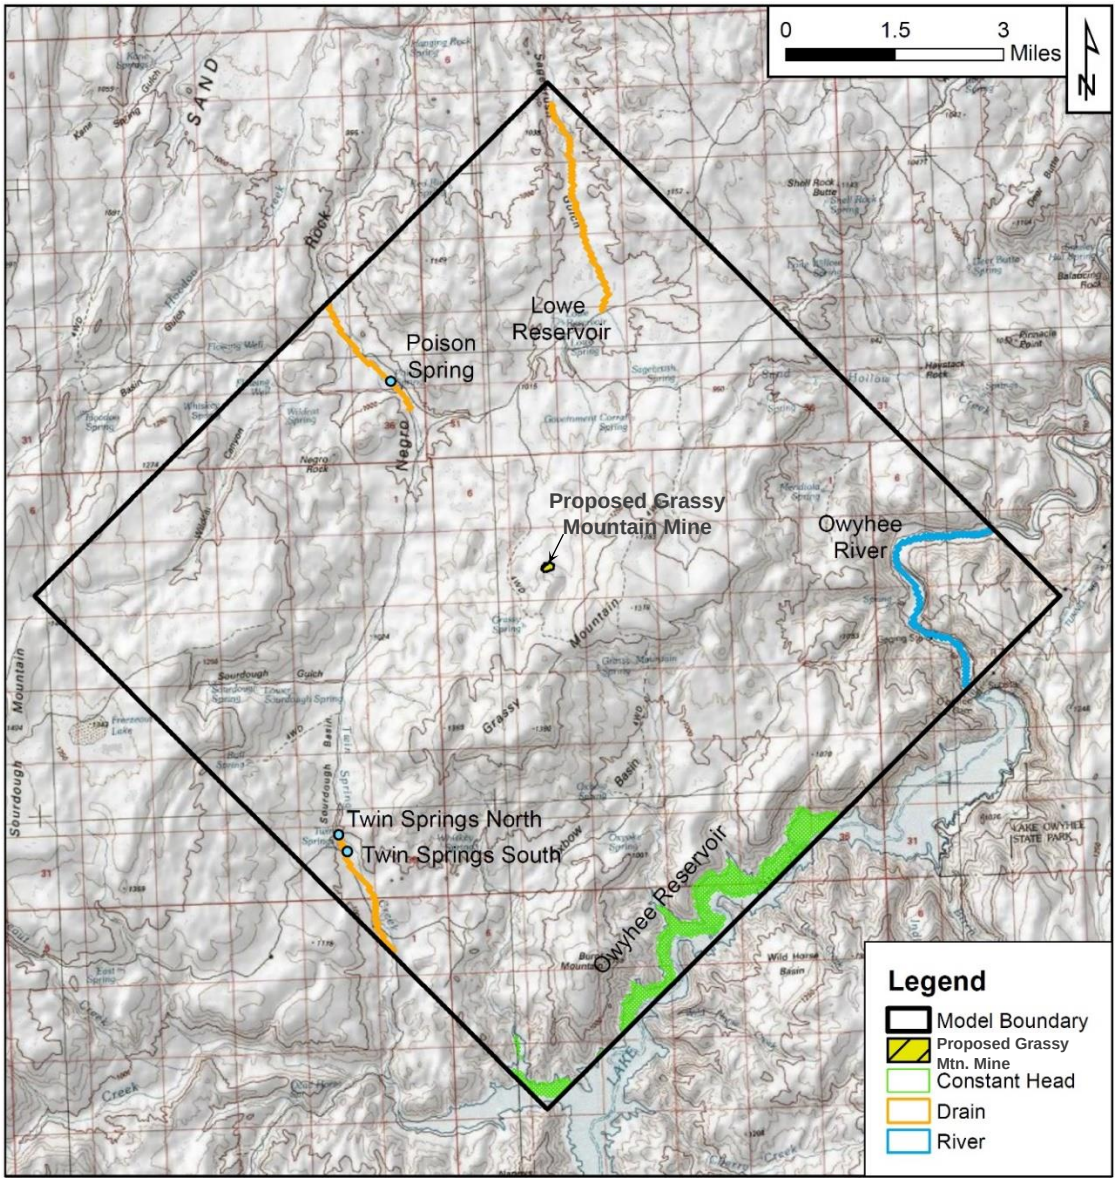

Figure 4. Model boundary conditions

5.3.1. Initial Conditions

The top elevation in layer 1 (surface topography) was assigned as the initial head condition for the model.

5.3.2. Constant Head Boundary

The constant head boundary fixes the groundwater elevation at a constant level and can be assigned to surface water features that fully contact the aquifer (McDonald and Harbaugh, 1988). A constant head boundary was assigned in all model layers to the portion of the Owyhee Reservoir that intercepts the southern model extent. A value of 2,655 feet elevation was assigned uniformly based on the topographic normal pool elevation for the reservoir (Ferns and Ramp, 1989).

5.3.3. River Boundary

Rivers can be gaining (effectively removing groundwater from the aquifer system) or losing (contributing flow to the aquifer system). A river boundary was assigned to the portion of the Owyhee River that intercepts the southeastern corner of the model in Layer 1. The river was assigned in the model as a single reach with the stage assigned at the DEM surface elevation value for model cells coinciding with the upstream end (approximately 2,391 feet elevation) and downstream end (approximately 2,305 feet elevation). A uniform value of 10 feet was assumed as the riverbed thickness and width for all river cells, and the length of the river was automatically assigned based on the model cell size. The hydraulic conductivity for the riverbed was assigned the same value as the adjacent alluvial aquifer material.

5.3.4. Drain Boundary

Drains only remove water from the model if the groundwater head rises above a fixed elevation. The rate of removal is proportional based on the groundwater head and the specified elevation (McDonald and Harbaugh, 1988). Drains can be used to simulate the effects of springs as local discharge locations.

A drain boundary condition was assigned to select spring features within Layer 1 of the model including Poison Spring (north of the resource area), Lowe Spring (northeast of the resource area), and Twin Springs (southwest of the resource area). Drain reaches were assigned in areas of low topography with stage elevations based on the DEM surface elevation coinciding with the springs. Inclusion of drains in the model (particularly in the area around Poison Spring) improved the overall water balance by allowing flow to exit the northern half of the model downgradient of Grassy Mountain.

5.3.5. No Flow Boundary

No-flow boundaries represent impervious surfaces. No-flow boundaries were automatically assigned at the bottom of the model (the base of Layer 3) and implicitly along the perimeter of the model when no other boundary condition was specified.

5.4. Hydraulic Properties

This section describes hydraulic properties assigned in the model including hydraulic conductivity and recharge. Recharge is a type of boundary condition that represents infiltration at the water table. In GV, recharge is categorized as a property.

5.4.1. Hydraulic Conductivity

Hydraulic conductivity was assigned in GV using a zone approach. Areas with the same hydraulic conductivity can be assigned to the same zone. Zones were created to loosely reflect surficial geology and were extrapolated to subsurface conditions.

Surficial geology was obtained from several sources (Calico Resources, 2015; Fern and Ramp, 1989; Ferns and Cummings, 1992; and Cummings, 1993). Maps were scanned, registered to the same coordinate system and projection as the model, and imported into GV to inform the assignment of hydraulic conductivity zones based on apparent similar lithologies. General zones were created to simulate shallow alluvium and sedimentary deposits primarily in drainage areas (Qal and Qls), sandstone, siltstone, and conglomerate (Tas and Tis), the undifferentiated Grassy Mountain Formation (Tgs), basalt (Tgb, Tnrb, Trsb), rhyodacite (Trd), alteration areas within and near the resource (designated by Calico Resources), and Kern tuff (Tkt). The hydraulic conductivity distribution assigned in the model to Layer 1, 2, and 3 are shown on Figure 5, Figure 6, and Figure 7, respectively.

Fault features or zones were not explicitly simulated in the model. Instead, hydraulic conductivity zones were assigned to attempt to match the overall distribution of groundwater flow and hydraulic gradient. When evaluating the trends in groundwater flow within the resource area, fault features appear to have some influence locally, but these effects appear to be dampened when looking at the overall trends on a more regional scale.

Initial values for hydraulic conductivity were based on the range of values reported from previous modeling (ABC, 1992) and the results of pumping tests. Values were adjusted during limited model calibration (described below) to achieve a match to the hydraulic gradient and overall direction of groundwater flow in the resource area (Table 4). K values for the materials listed below are consistent with those provided in Freeze and Cherry, 1979 and Fitts 2013.

Table 4. Model hydraulic conductivity (ft/day)

Zone	Description	Kx = Ky	Kz
1	Basin deposits (siltstone, sandstone, unconsolidated)	0.214	0.105
2	Alluvium (Qal, Qls)	5.57	2.18
3	Siltstone, sandstone (Tis)	0.676	0.347
4	Resistent topography and basalt	0.001	0.001
5	Altered zones (within and near deposit)	0.0031	0.0031
6	Rhyodacite dome	0.0007	0.0007
7	Deeper deposits and Kern Tuff (Tkt)	0.0025	0.0013
8	Higher topography region to south	0.0025	0.0025

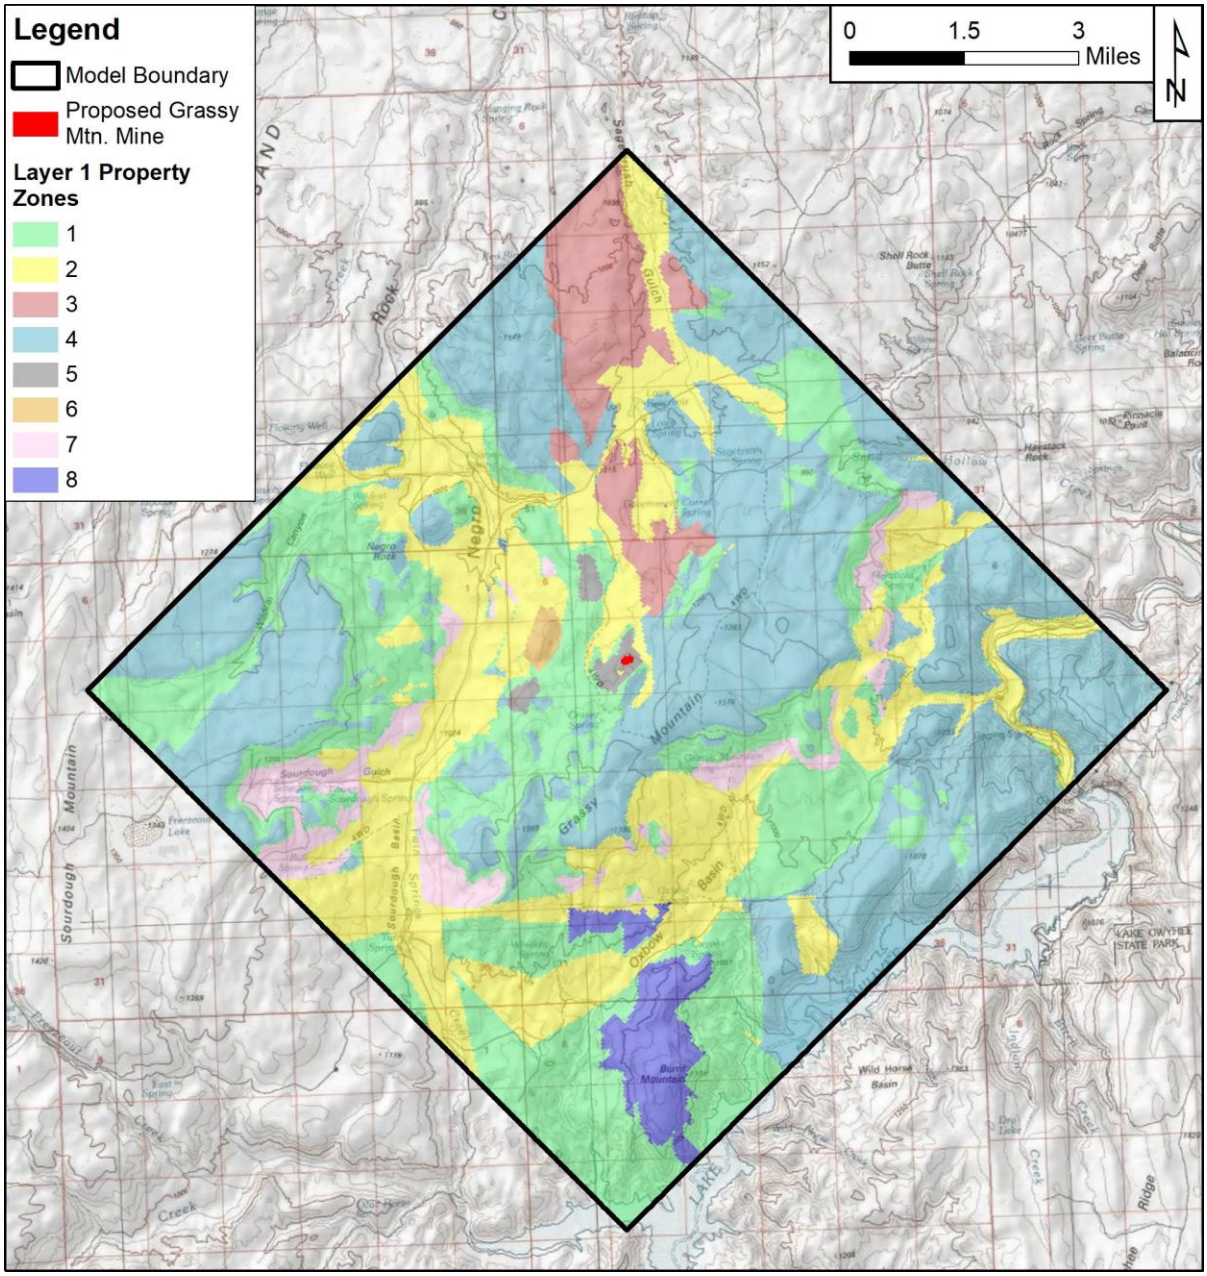

Figure 5. Layer 1 property zones

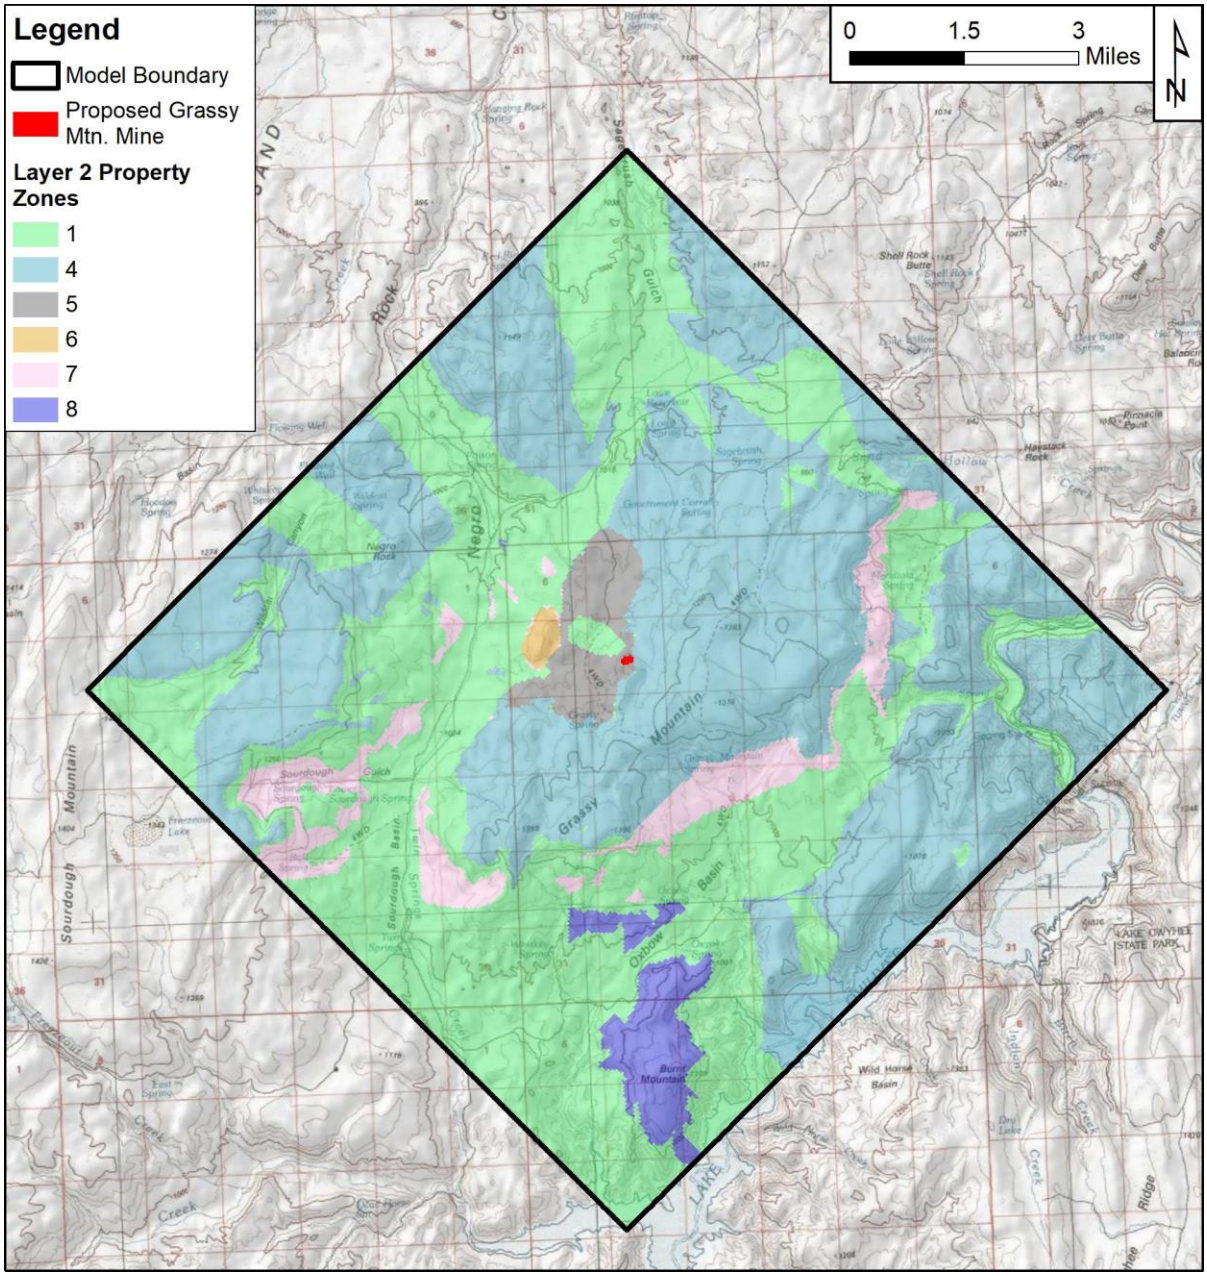

Figure 6. Layer 2 property zones

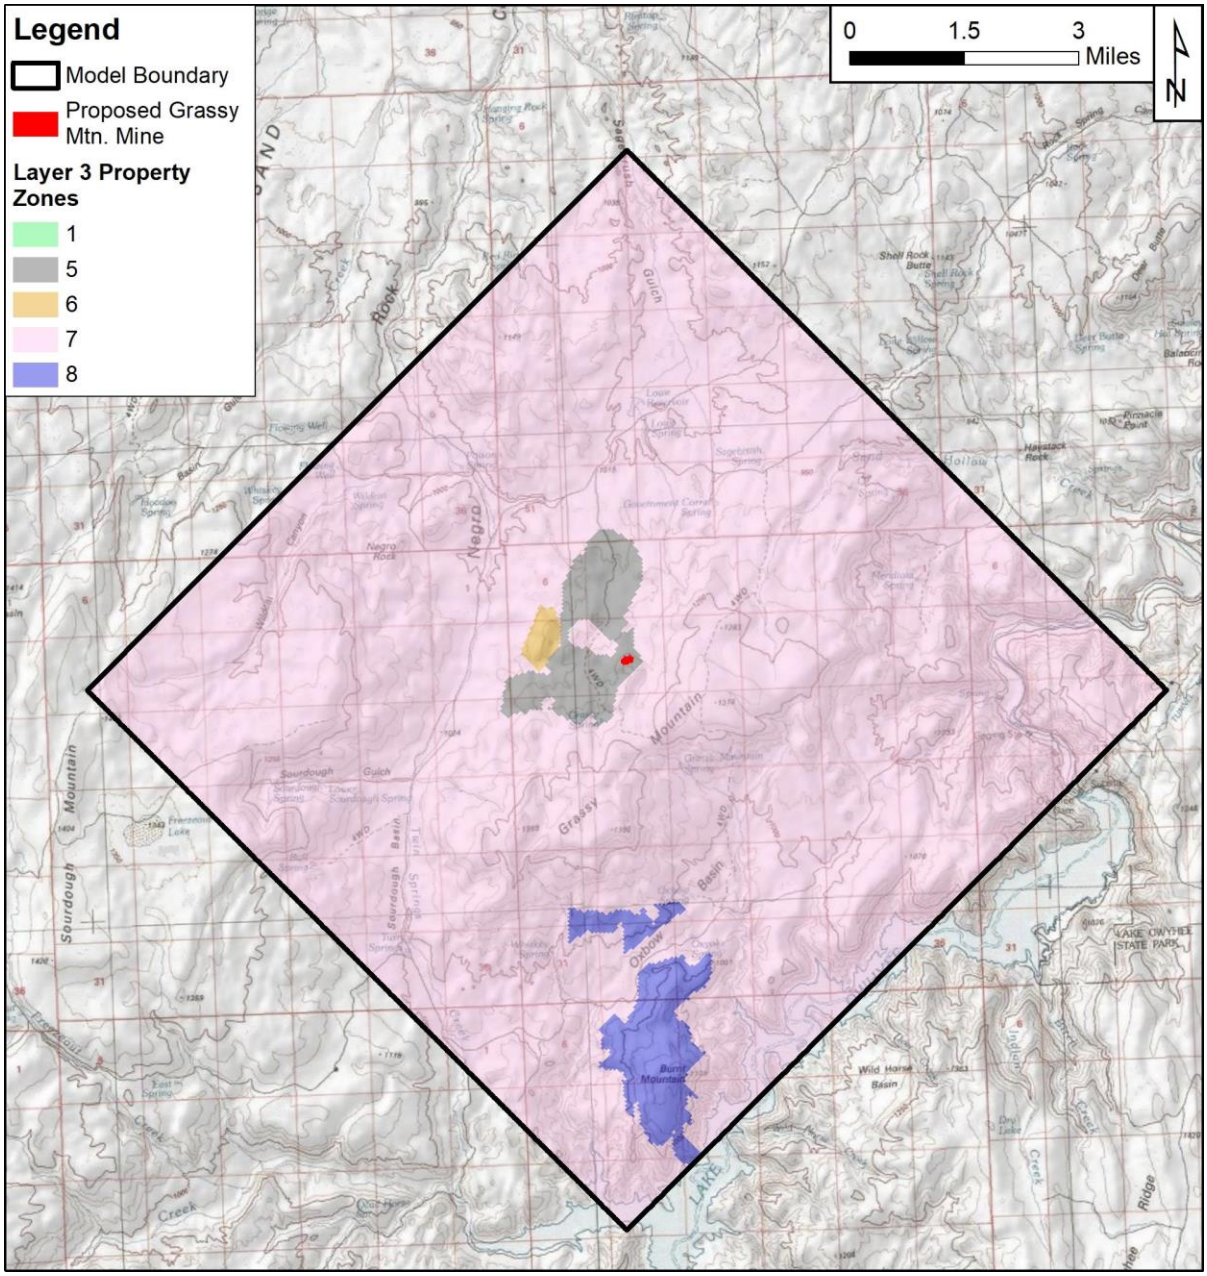

Figure 7. Layer 3 property zones

In general, surface geology was assigned to Layer 1, based on its relatively shallow thickness. Assignment and correlation of subsurface geology is complicated by the overall lack of information for most areas in the model and the high degree of heterogeneity (both laterally and vertically). Lithology types interpreted to be more resistant at the surface (i.e., rhyodacite dome, Kern Tuff, and some regions for basalt) were assumed to also be present

at greater depth and were extended into Layer 2 and Layer 3. However, the hydraulic conductivity assigned in the model to various zones was guided largely by the resulting match between model simulated and measured heads (discussed in the section on model calibration below).

5.4.2. Storage Parameters

For the transient model, storage parameters including specific storage, specific yield, and porosity were assigned to necessary property zones. The values were initially assigned in GV using results from pumping tests and representative values from literature (Domenico 1965). Values were adjusted during limited model calibration (see section 5.5) using manual adjustments and PEST to achieve an improved match between model simulated and measured heads. The storage values assigned to each zone are presented as Table 5. The same zones used for the hydraulic conductivity were used for the storage values (Figure 5, Figure 6, and Figure 7).

Table 5. Model storage values (dimensionless)

Zone	Description	Specific Storage	Specific Yield	Porosity
1	Basin deposits (siltstone, sandstone, unconsolidated)	2.62E-04	0.30	0.20
2	Alluvium (Qal, Qls)	5.00E-03	0.13	0.30
3	Siltstone, sandstone (Tis)	5.00E-03	0.30	0.20
4	Resistent topography and basalt	5.00E-05	0.05	0.08
5	Altered zones (within and near deposit)	5.00E-05	0.11	0.10
6	Rhyodacite dome	7.14E-05	0.08	0.08
7	Deeper deposits and Kern Tuff (Tkt)	1.74E-03	0.30	0.06
8	Higher topography region to south	3.35E-03	0.05	0.06

5.4.3. Recharge

Recharge was assigned to Layer 1 as zones to simulate infiltration that reaches the groundwater table (Figure 8). Conceptually, higher elevations are expected to receive higher rates of recharge compared to basins or areas of lower elevation typically associated with discharge regions. Therefore, a higher rate of recharge (0.45 in/yr) was assigned a portion of Grassy Mountain, Sourdough Mountain, and a higher elevation region to the south (shown in yellow in the figure). Recharge assignment was arbitrary as the locations/ delineation of separate recharge areas is not a known condition. Lower recharge (approximately 0.07 in/yr) was assigned elsewhere throughout the model based on balancing the water budget of the model with the observed total flow of springs. Recharge was not modified during the limited calibration process but was evaluated during limited sensitivity runs.

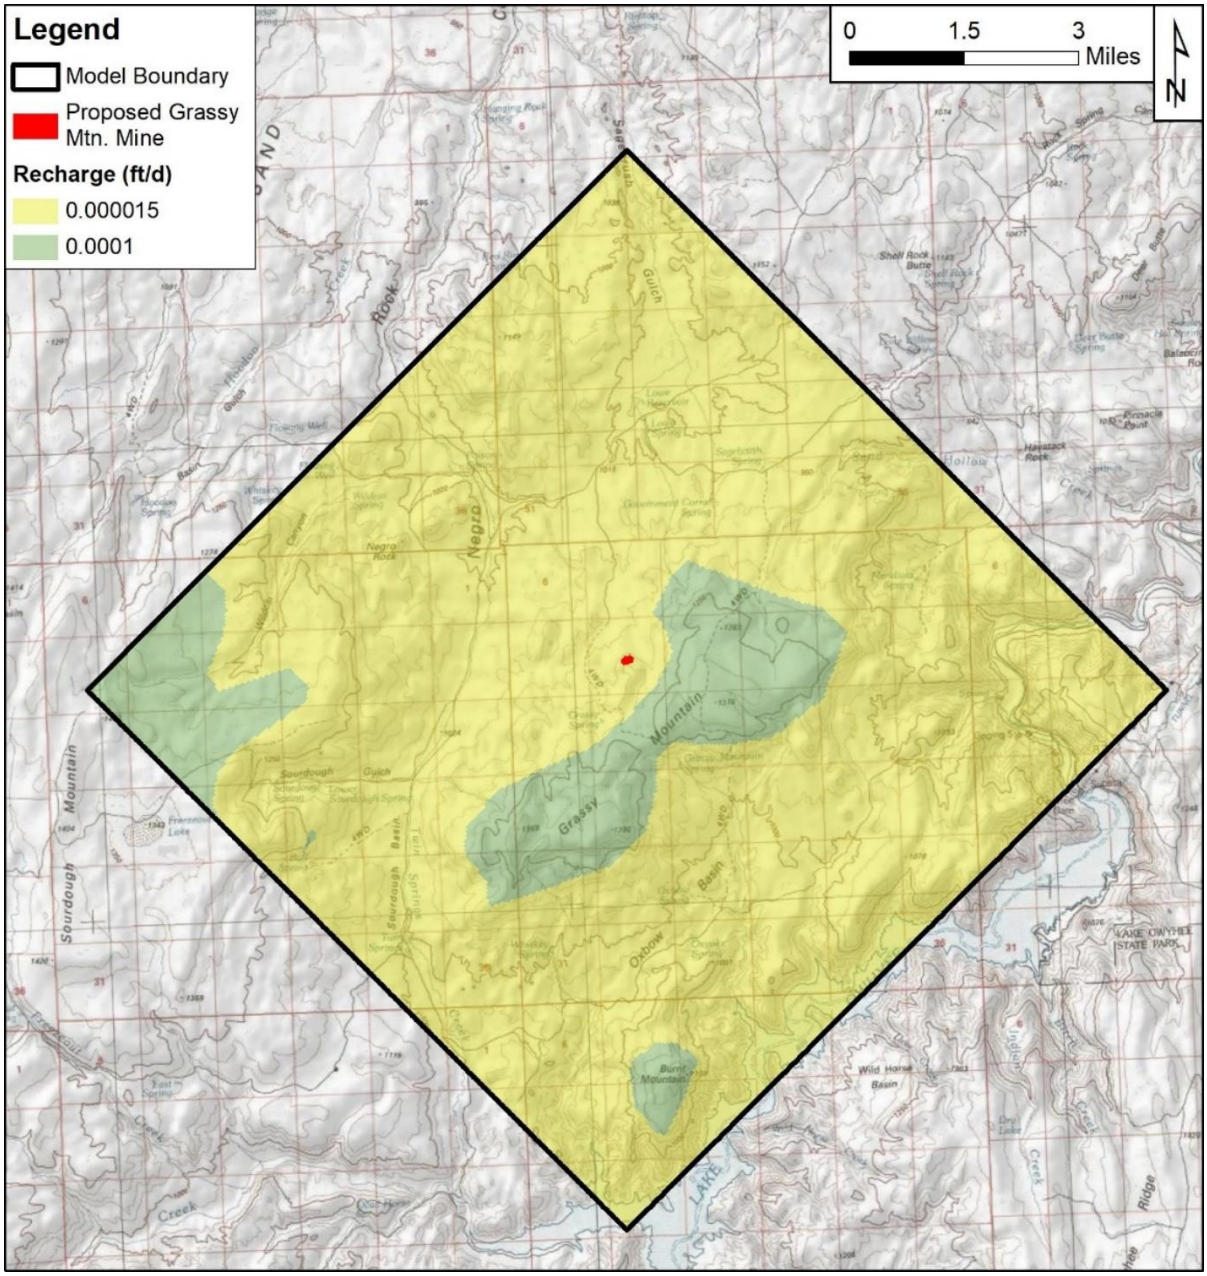

Figure 8. Model recharge distribution

5.5. Limited Calibration

Limited model calibration was performed using a combination of both manual and automated parameter estimation techniques. One method of calibration is to compare the degree to which the simulated groundwater heads agree with measured values. The model,

by necessity, is an oversimplification of actual conditions but is considered to be commensurate with its intended use for baseline level estimates of groundwater flow, water balance, dewatering rates, and drawdown associated with groundwater production.

Average potentiometric surface and groundwater elevations at individual wells in the shallow zone for 2016 conditions were used to guide the model development and limited calibration process. Overall, the potentiometric surface and hydraulic gradient in the vicinity of Grassy Mountain have remained relatively consistent with little variation over time based on monitoring in the shallow zone. Therefore, the use of average 2016 conditions is considered appropriate for modeling purposes. The model, as currently calibrated, does not reproduce the heads measured in the deep wells and VWP sensors.

Groundwater elevations were imported into the model as calibration targets based on the well coordinate, screen mid-point elevation, and measured groundwater elevation. Wells were assigned automatically in the model to the layer corresponding with the screen mid-point elevation. MODFLOW calibration targets are summarized in Appendix C. MODFLOW input and output files for the base case, sensitivity runs, PEST, and dewatering scenario are provided in Appendix D on a memory device.

5.5.1. Manual Calibration

Manual calibration involves changing one or more model parameters at a time, running the model, and assessing the results. The calibration process continues until a reasonable match between model simulated and measured (observed) heads and/or flux conditions is reached.

This process is inherently non-unique and is strongly determined by the model setup (i.e., parameter zonation and value assignment). For example, a given match to the observed heads could result from a particular set of hydraulic conductivity values at a given recharge rate. The same head match could result from a different set of hydraulic conductivity and recharge values. For this reason, both the observed groundwater heads, overall potentiometric surface, hydraulic gradients, and expected (order-of-magnitude) range in the overall water balance for the region were considered during the calibration process.

5.5.2. **Parameter Estimation (PEST)**

The parameter estimation software (PEST, Version 13.6) was used to optimize select model inputs including hydraulic conductivity near the proposed Grassy Mountain Mine (zones 1, 4, and 5) and drain conductance (all reaches) to improve the model's match to measured groundwater elevations near the resource for the steady state model. During the calibration of the transient model additional PEST calibrations were performed to calibrate all hydraulic

conductivity and storativity values. PEST is an optimization program based on nonlinear parameter estimation techniques[5], distributed by Watermark Numerical Computing (2010).

Model input parameters are selected for optimization by specifying a lower and upper bound for each parameter based on the expected, plausible range of values. For example, hydraulic conductivity may span several orders of magnitude, assigned with lower and upper ranges. PEST then adjusts parameters within the specified range through successive iterations to lower the total error (or objective function) in the model. The total error in the model is the sum of the residual errors (i.e., the difference between each simulated head versus the measured head at a given location) based on user-defined targets. PEST has been incorporated into the GV interface, and all PEST simulations were performed using GV.

5.6. Model Results

Overall, the model simulates groundwater flow on a regional scale that generally follows topography. Groundwater flow from the resource area is predominantly to the northwest within the hydraulic basin north of Grassy Mountain (Figure 9). The model also represents the general direction of groundwater flow and horizontal hydraulic gradient within the resource area in the shallow zone (Figure 10), based on comparison of 2016 groundwater contours to model simulated heads within Layer 2. Model simulated contours are shown in blue, overlain on the 2016 contours in red.

Layer 1 was predominantly dry in most areas of the model, attributed to the relatively thin layer, effects of boundary condition assignment in the model (particularly drains), and hydraulic conductivity values. For example, vertical hydraulic conductivity is not well represented in the model.

Layer 3 does not contain head calibration targets; therefore, the overall degree to which model heads represent actual conditions could not be evaluated. However, the model does not simulate the observed heads in the deep wells and VWP units.

[5] Gauss-Marquardt-Levenberg algorithm

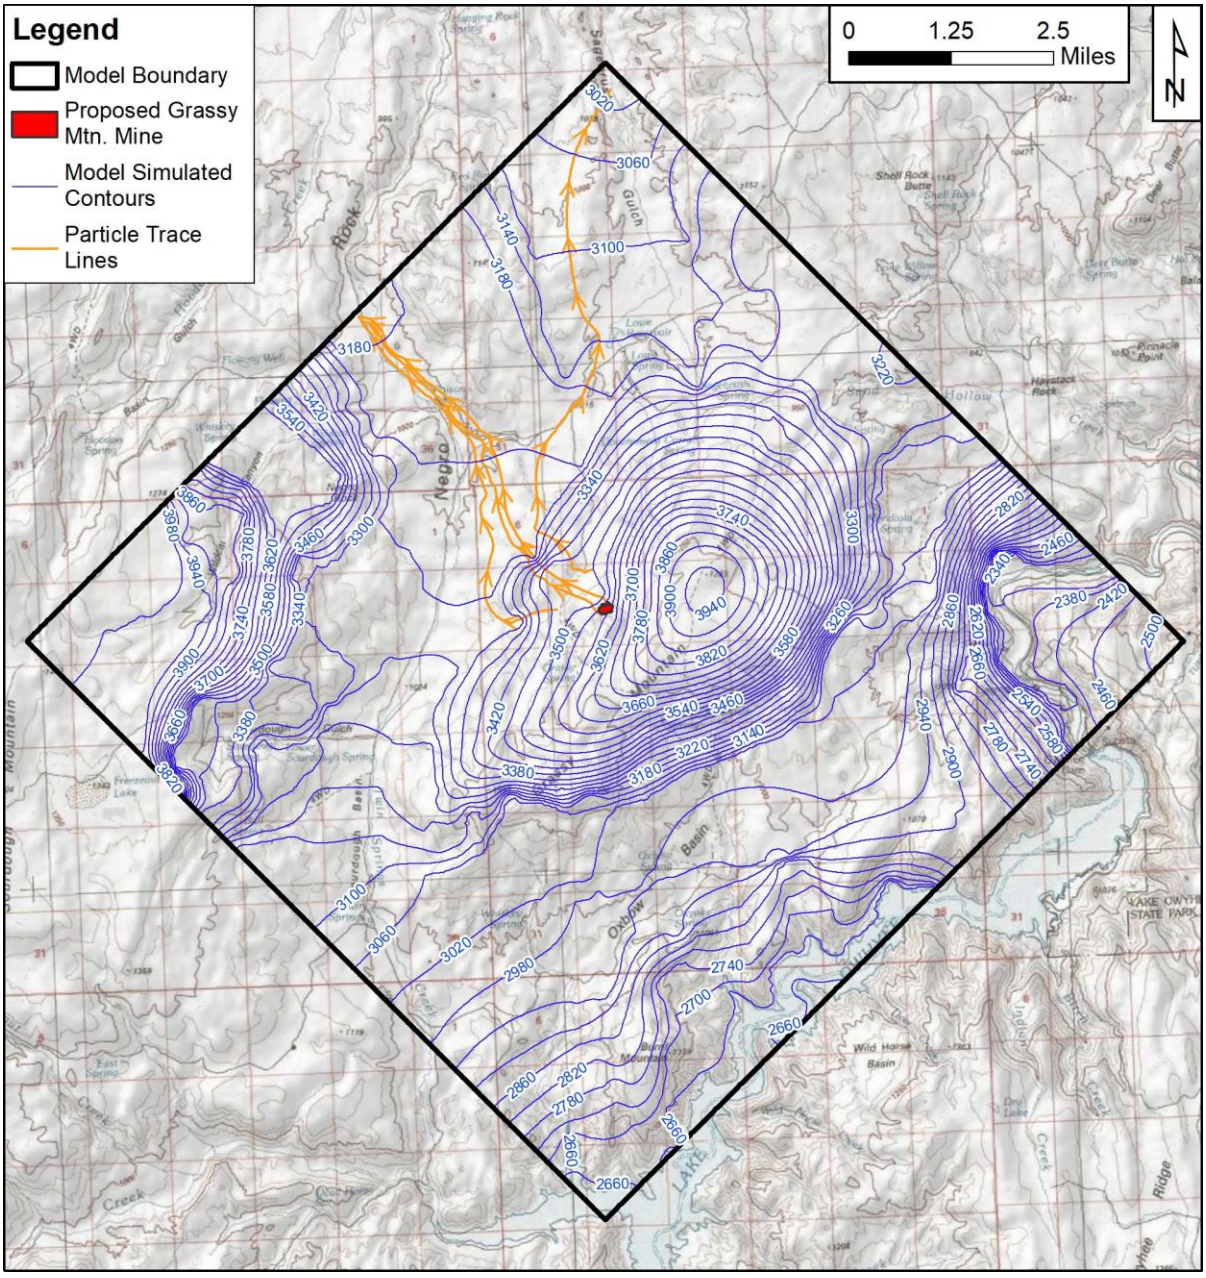

Figure 9. Model simulated groundwater contours (layer 2)

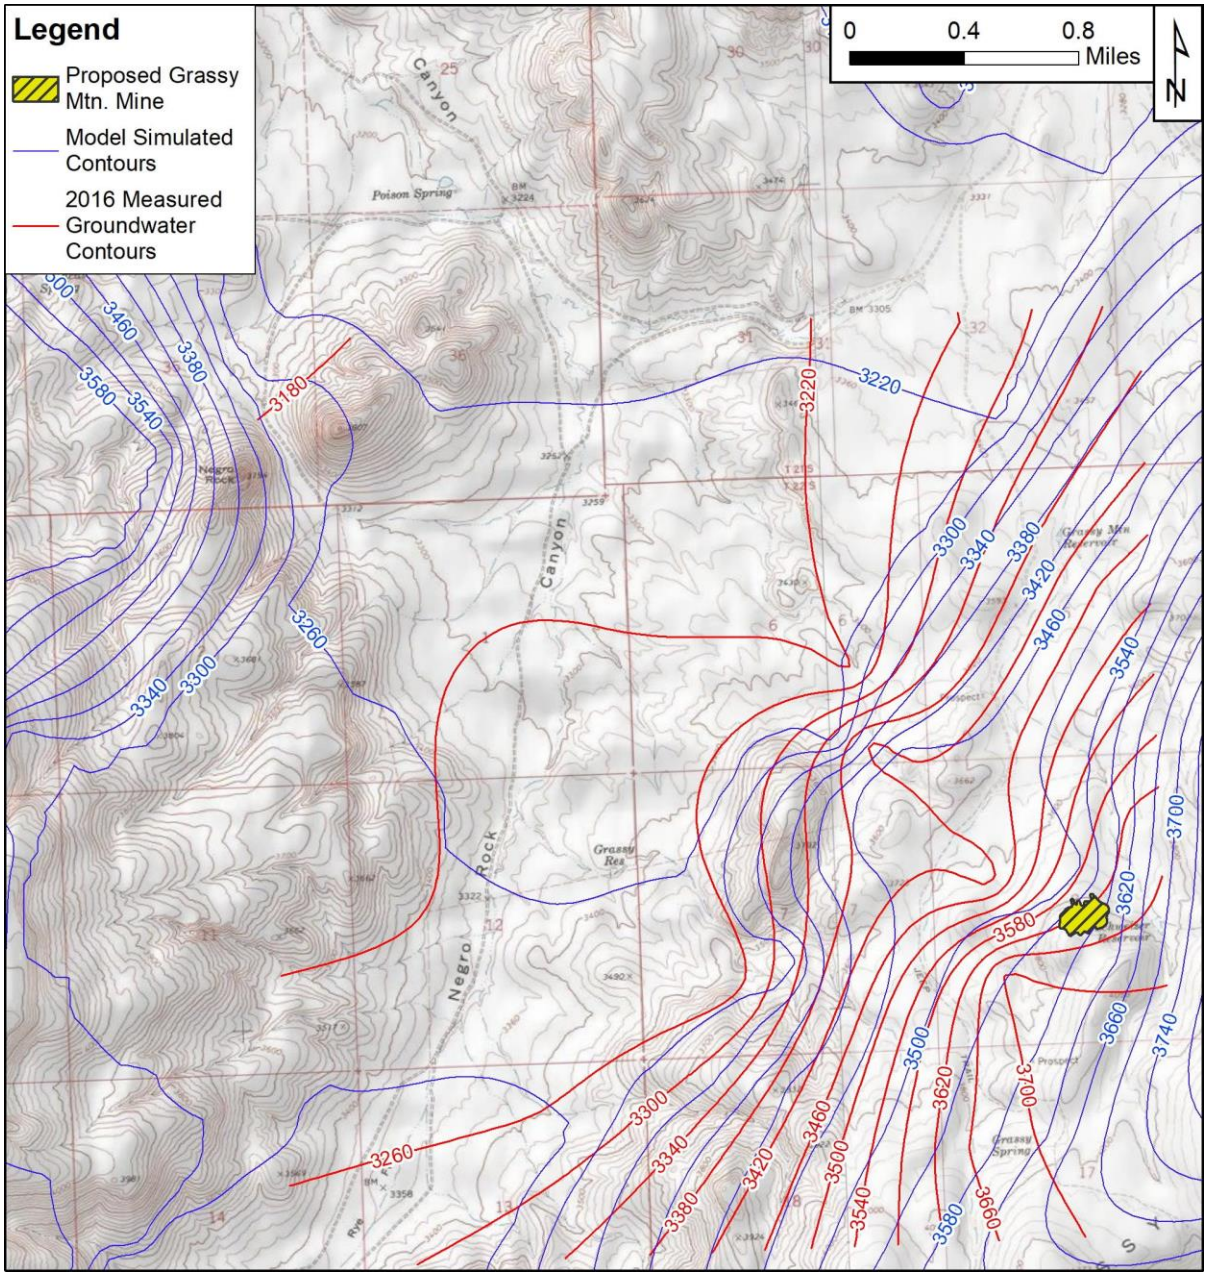

Figure 10. Modeled heads (layer 2) compared to 2016 contours

In general, the model typically simulated measured heads within +/- 45 feet, with some outliers with more or less associated error. The lowest error was less than one foot, and the highest error was 113 feet. The targets assigned to Layer 1 also contribute to the errors in the model. Posted residuals in

Figure 11 show the difference between model computed heads and measured heads for layer 1 and the residuals for layer 2 are presented in Figure 12. Residuals in blue indicate the model under-predicts measured heads, and the residuals in red indicate the model over-predicts heads.

Discrepancies between model simulated and measured heads are attributed to the combination of several, potential factors including the coarse layer resolution in Layer 2, heterogeneity effects not simulated in the model, hydraulic conductivity zonation, non-unique fit between model inputs including recharge and hydraulic conductivity, and representation of head targets in the model as a single point within a single layer. Model calibration statistics for both layers 1 and 2 are summarized in Table 6.

Table 6. Model simulated vs. measured heads

Residual Mean	11.99
Absolute Residual Mean	42.57

Scaled Residual Mean	0.02

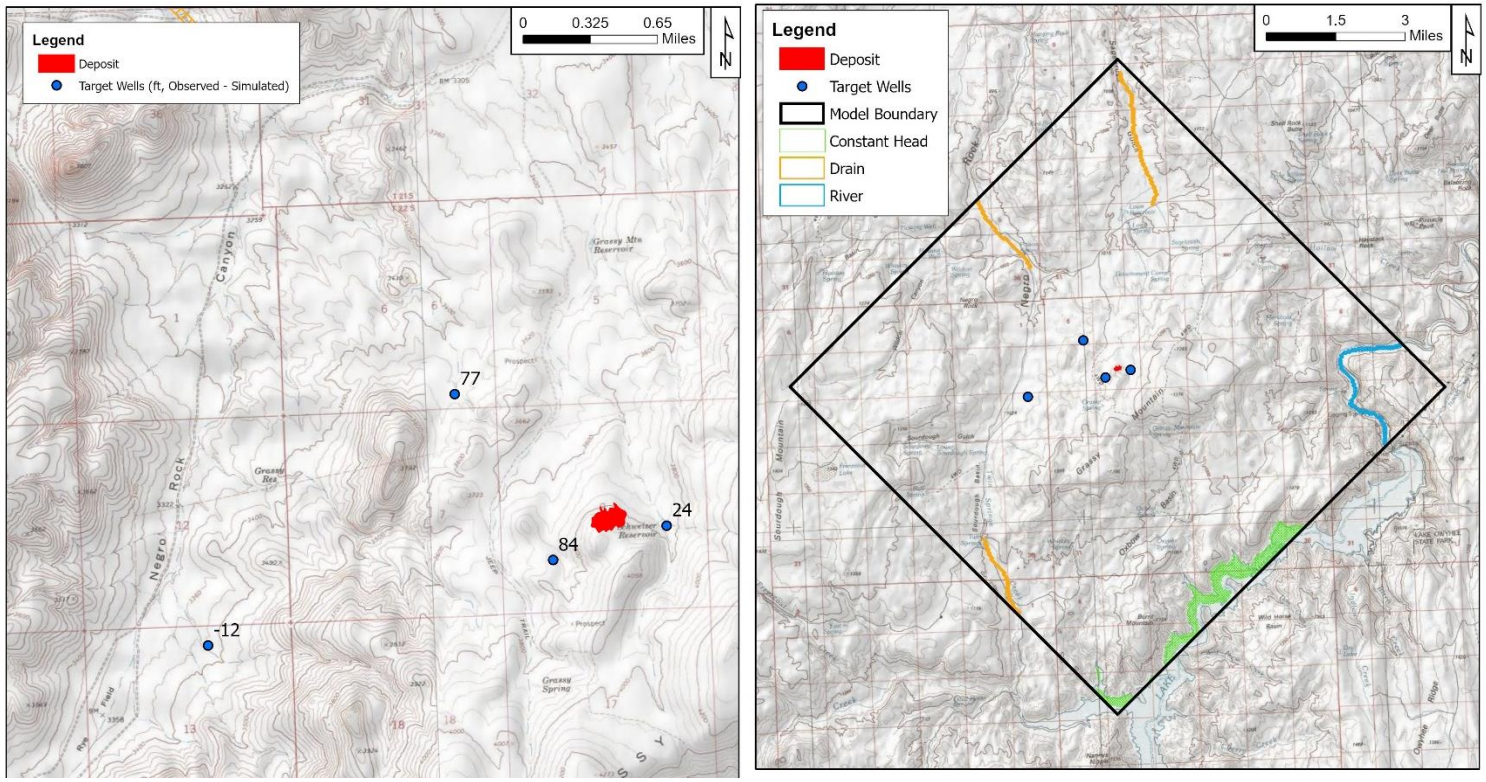

Figure 11. Model layer 1 residual head values (left) target well location (right).

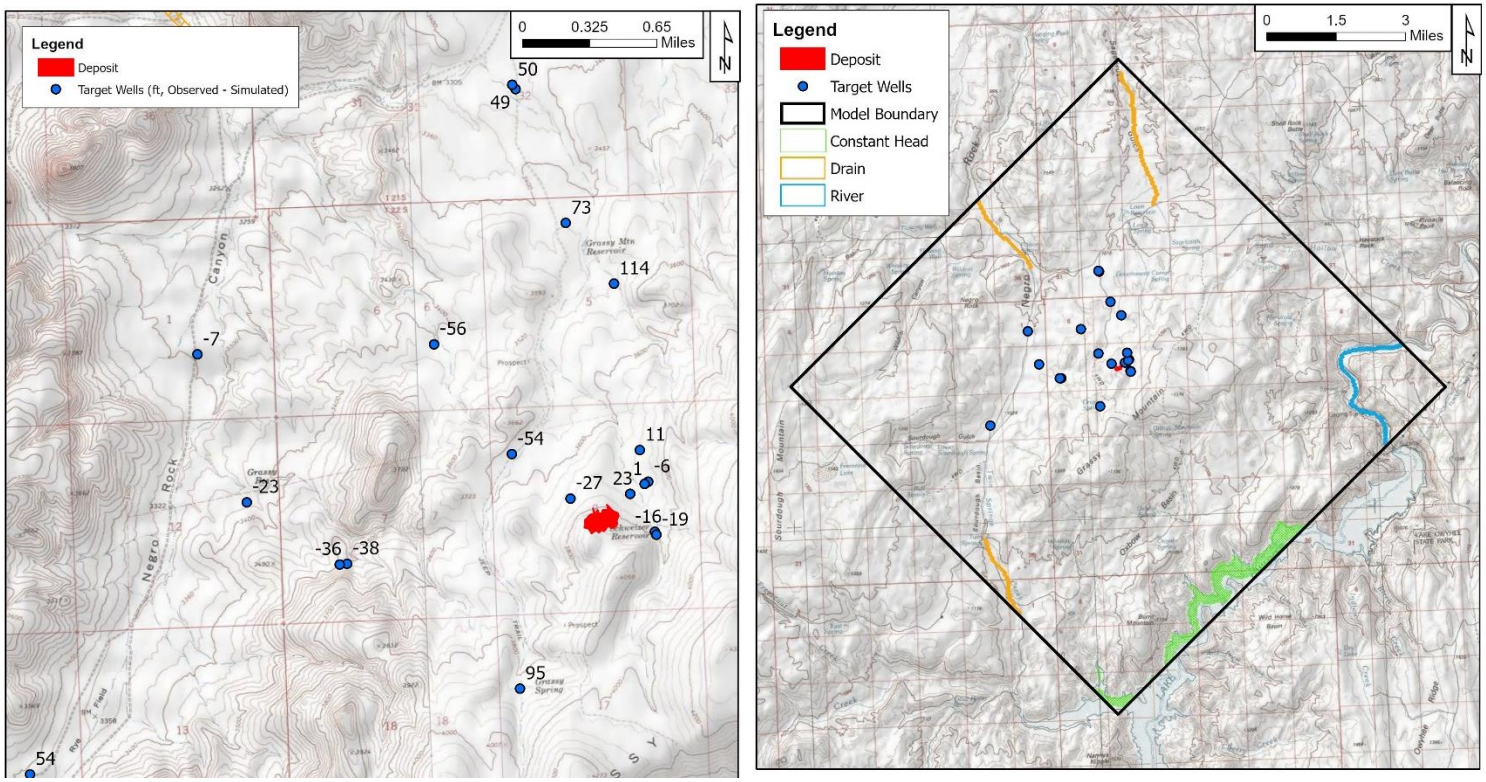

Figure 12. Model layer 2 residual head values(left) target well locations (right)

As with any model, there is room for improvement in the overall model calibration. The model might be improved through one or more of the following approaches:

- Use of a finite element model could potentially better represent the steep vertical gradients near the resource area and compartmentalization effects apparent in the groundwater elevation datasets.

- Additional discretization (horizontal zones and/or vertical layers) and anisotropy could be incorporated to allow more variation in assigned aquifer properties and greater control on changing values in the model to match observed conditions (i.e., individual well responses).

- Geostatistical methods could be evaluated to populate aquifer parameters such as hydraulic conductivity in areas of the model where limited information exists. These methods also could be used to potentially obtain a better match in areas where information does exist but the model is not at a resolution/calibrated to simulate the observed conditions. For example, use of the PEST automatic parameter estimation technique coupled with a geostatistical 'pilot points' approach based on kriging[6] could allow assignment of hydraulic conductivity that is not tied to property zones. Currently, hydraulic conductivity is assigned in the model based on inferred zones expected to have similar properties.

The model calculated volumes for inflow (recharge and river leakage) and outflow (constant head, drains, and river leakage) are summarized in Table 7 below. Recharge represents the greatest inflow into the model, with minor river leakage effects. Groundwater exits the model through constant head cells assigned to the Owyhee Reservoir, drain cells assigned to select spring features, and, to a lesser extent, through river cells assigned to the Owyhee River. The overall error in the water balance in the model is -0.01 percent. An acceptable error balance is typically regarded as less than 0.1 percent (Anderson and Woessner, 1992).

[6] Pilot points are assigned by the user at specific locations in the model based on the level of available information on hydraulic properties. The parameter estimation process uses a regularized inversion numerical approach to obtain the best fit to the solution such as observed or measured heads (Doherty and Hunt, 2010).

Table 7. Model water budget

Parameter	Inflow (ft^3/day)	Inflow (gpm)	Outflow (ft^3/day)	Outflow (gpm)
Storage	0	0	0	0
Constant Head	0	0	38865.47	201.9115
Wells	0	0	0	0
Drains	0	0	22725.53	118.0623
River Leakage	3232.565	16.79362	12872.29	66.87331
Recharge	71221.4	370.0051	0	0
Total	74453.97	386.7987	74463.29	386.8471
% Discrepancy	0.01			

5.7. Sensitivity Analysis

A limited sensitivity analysis was performed by varying hydraulic conductivity and recharge from the base model case. The purpose of the sensitivity assessment was to bracket the model predictions within a reasonable range of model input values. This analysis was used prior to transient calibration and the base target statistics are slightly different than values presented above. This evaluation was intended to provide some additional context for the model predictions.

Four, separate scenarios were evaluated:

- Sensitivity Run 1 – Hydraulic conductivity for all zones was increased by 2x. This run resulted in model simulated heads under-predicting measured heads at all locations.

- Sensitivity Run 2 – Hydraulic conductivity for all zones was decreased by 2x. This run resulted in model simulated heads over-predicting measured heads at nearly all locations.

- Sensitivity Run 3 – Recharge was increased by 2x. This run resulted in model simulated heads over-predicting measured heads at all locations.

- Sensitivity Run 4 – Recharge was decreased by 2x. This run resulted in model simulated heads under-predicting measured heads at all locations.

The overall direction of groundwater flow is similar for all cases; however, the magnitude of the model errors is considerably greater compared to the base case model (Table 8).

Table 8. Summary of sensitivity analysis

Statistic	Base Model	Sensitivity Run 1	Sensitivity Run 2	Sensitivity Run 3	Sensitivity Run 4
		2x greater hydraulic conductivity	2x lower hydraulic conductivity	2x higher recharge	2x lower recharge
Residual Mean	10.98	170.35	-249.03	-234.12	173.41
Absolute Residual Mean	45.83	176.96	278.72	260.13	180.01
Residual Std. Deviation	53.93	130.82	271.55	251.15	133.64
Sum of Squares	72,696	1,107,174	3,258,175	2,829,320	1,150,329
RMS Error	55.04	214.78	368.45	343.35	218.93
Min. Residual	-78.98	-74.42	-686.52	-648.67	-74.42
Max. Residual	113.94	406.12	113.94	113.94	412.36
Number of Observations	24	24	24	24	24
Range in Observations	498	498	498	498	498
Scaled Residual Std. Deviation	0.11	0.26	0.55	0.50	0.27
Scaled Absolute Residual Mean	0.09	0.36	0.56	0.52	0.36
Scaled RMS Error	0.11	0.43	0.74	0.69	0.44
Scaled Residual Mean	0.02	0.34	-0.50	-0.47	0.35

These results support the general order-of-magnitude values for hydraulic conductivity and recharge rates used in the base model case. Sensitivity model files are included in Appendix D.

5.8. Dewatering Scenario

5.8.1. Steady State Dewatering

Dewatering was simulated in the model by including pumping wells around the perimeter of the proposed Grassy Mountain Mine (**Error! Reference source not found.**). Four wells (numbered D-1 through D-4) with an extraction rate of 5 gpm each (20 gpm total) were simulated in Layer 2 to represent steady-state (i.e., non-time varying) pumping conditions. Wells are simulated as fully-penetrating, extending through the entire thickness of Layer 2. In reality, dewatering would be performed using wells that are not likely to be completed through the entire vertical section required for dewatering. In that case, additional vertical flow components would be expected to result in additional drawdown beyond that predicted for the fully penetrating well, with only horizontal flow effects simulated.

The model simulates depressing the water table to approximately 2,950 feet to 3,100 feet within the resource footprint, below the approximate target elevation of 3,100 feet, with all four wells pumping simultaneously. The cells in purple in Figure 13are dewatered (i.e., the head calculated in the model is below this layer).

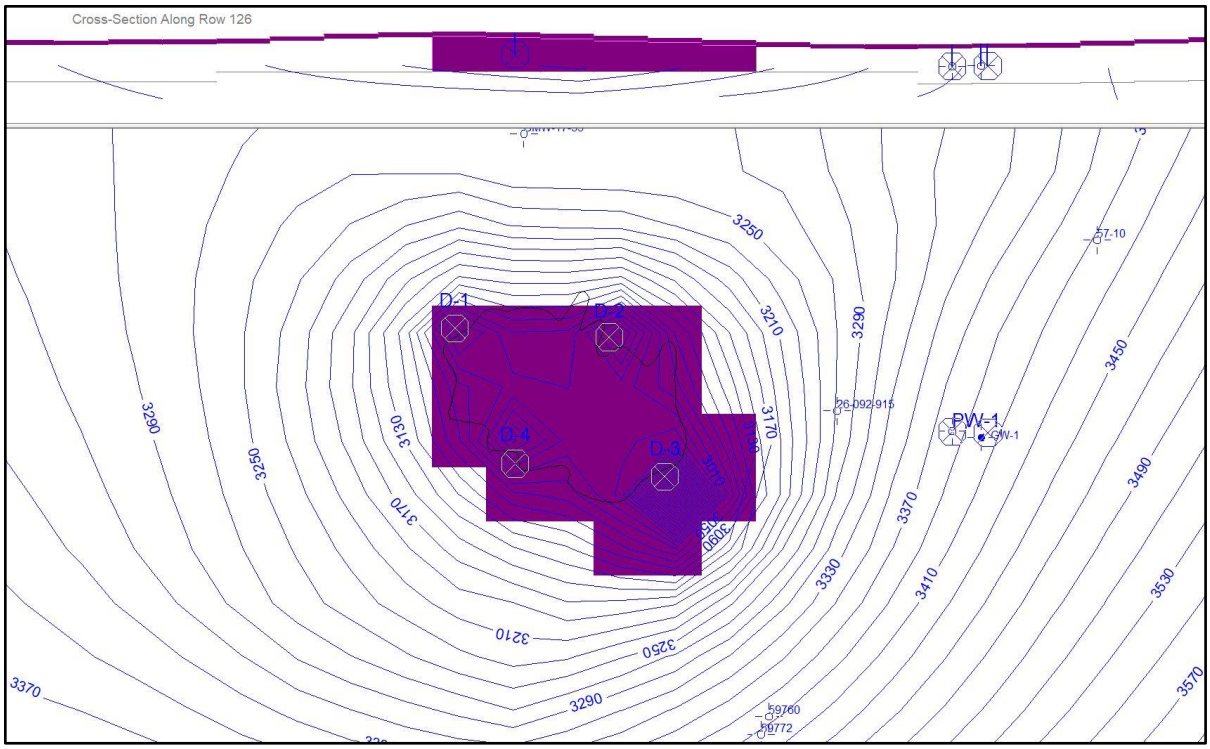

Figure 13. Dewatering simulation

5.8.2. Transient Dewatering

The same dewatering flows from the four dewatering wells was simulated in the transient model. The transient model predicted it would take thousands of years for the mine to be dewatered at a total pumping rate of 20 gpm. The transient model was then set up to pump for 10 years total with higher flows for 70 days and relatively lower flow for the remaining 10 years. An additional dewatering well was added to the center of the proposed Grassy Mountain Mine. The flows and a plot of predicted water levels from each dewatering well used to dewater the mine are presented below in Table 9 and Figure 14. A map of the wells, the area of dewatering (indicated by purple cells), and water level contours is provided below as Figure 15.

Table 9. Transient model simulated dewatering well flows

Dewatering Well	First 70 Days Flow (gpm)	Remaining 10 Years Flow (gpm)
D-1	80	15
D-2	80	10
D-3	120	7.5
D-4	120	15
D-5	80	10
Combined Flow	480	57.5

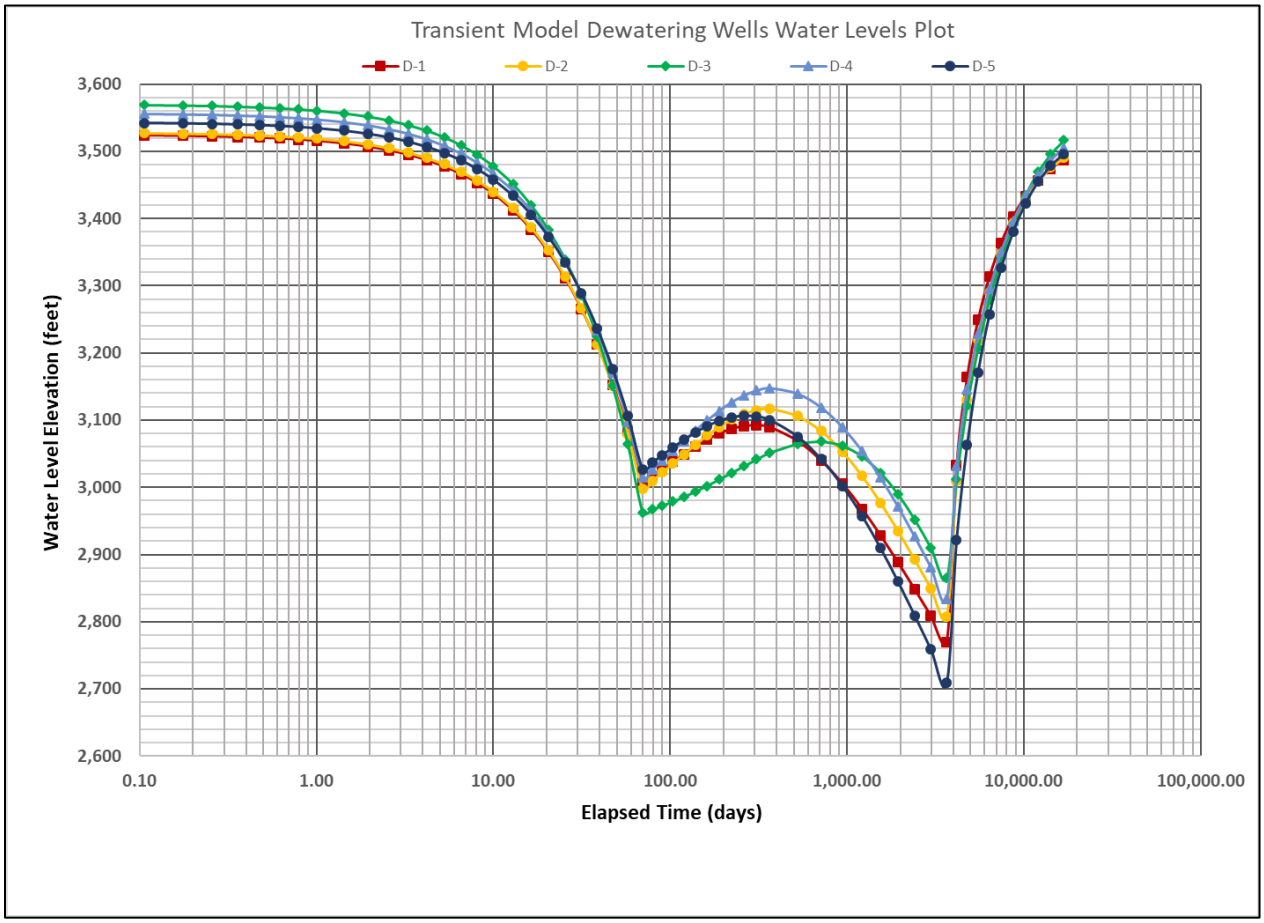

Figure 14. Transient model dewatering wells water levels plot

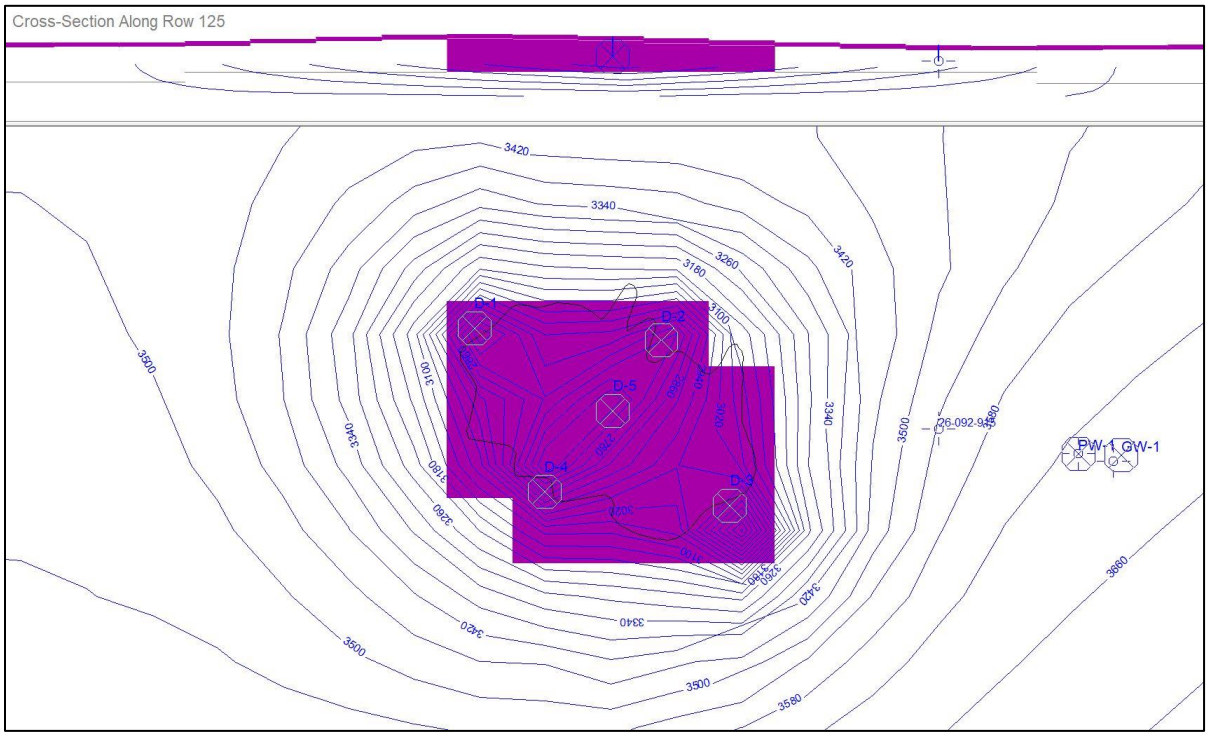

Figure 15. Transient model dewatering wells and water level contours (10 yrs)

5.8.3. Other Factors Influencing Dewatering

The data collected from monitoring wells, vibrating wire piezometers, and other bores drilled in and near the proposed Grassy Mountain Mine demonstrate that the groundwater flow in this highly faulted and silicified zone is highly restricted, and water levels are relatively deeper than in wells completed further from the mine. In some of the silicified zone, the aquifer is unable to produce any water. This numerical model, calibrated to the shallower and more consistent surrounding well water levels, is meant to show a maximum amount of dewatering possible. It is likely, where water is encountered in the deeper zones of the proposed Grassy Mountain Mine, that the lower flows (57.5 gpm) modeled to keep the water levels down after the first 70 days of pumping will be more than adequate for dewatering. Due to the compartmentalized nature of the aquifer surrounding the mine, it is possible larger flows of water may be initially encountered for short periods (days or weeks).

5.9. Groundwater Production for Mine Operations Scenario

5.9.1. Transient Modeling Results

Production well pumping was modeled simultaneously with the transient model dewatering pumping as described above for a 10-year period to predict drawdown effects on the aquifer system. The model simulated production wells 3,4, and 5 (mapped on Figure 1) pumping 106.67 gpm each for a total of 320 gpm. The drawdown from the dewatering and production wells pumping is mapped in Figure 16. After ten years of pumping, the model predicts a little over 2 feet of drawdown at Lowe Spring and zero drawdown at Poison Spring.

The model was designed to run a total of 368,650 days, approximately 1,000 years after pumping ceases to model recovery. After ten years of pumping, when the wells cease pumping, the area of impact continues to migrate outward due the slow equilibration of the cone of depression. After approximately 10,000 days of recovery the model predicts a residual drawdown of over 20 feet near the production wells, approximately 10 feet of drawdown at Lowe Spring, and less than 0.5 feet of drawdown at Poison Spring. A plot of residual drawdown remaining after approximately 10,000 days of recovery is presented as Figure 17.

Plots of drawdown at the production wells and springs (Lowe Spring and Poison Spring) are provided as Figure 18 and Figure 19, respectively. The maximum drawdown in the production wells is 212 feet after ten years in Well 5. Lowe Spring was affected the most by the cone of depression with the water levels in layer 1 drawing down approximately 2 feet until that layer was dry, and layer 2 drawing down at most 11 feet.

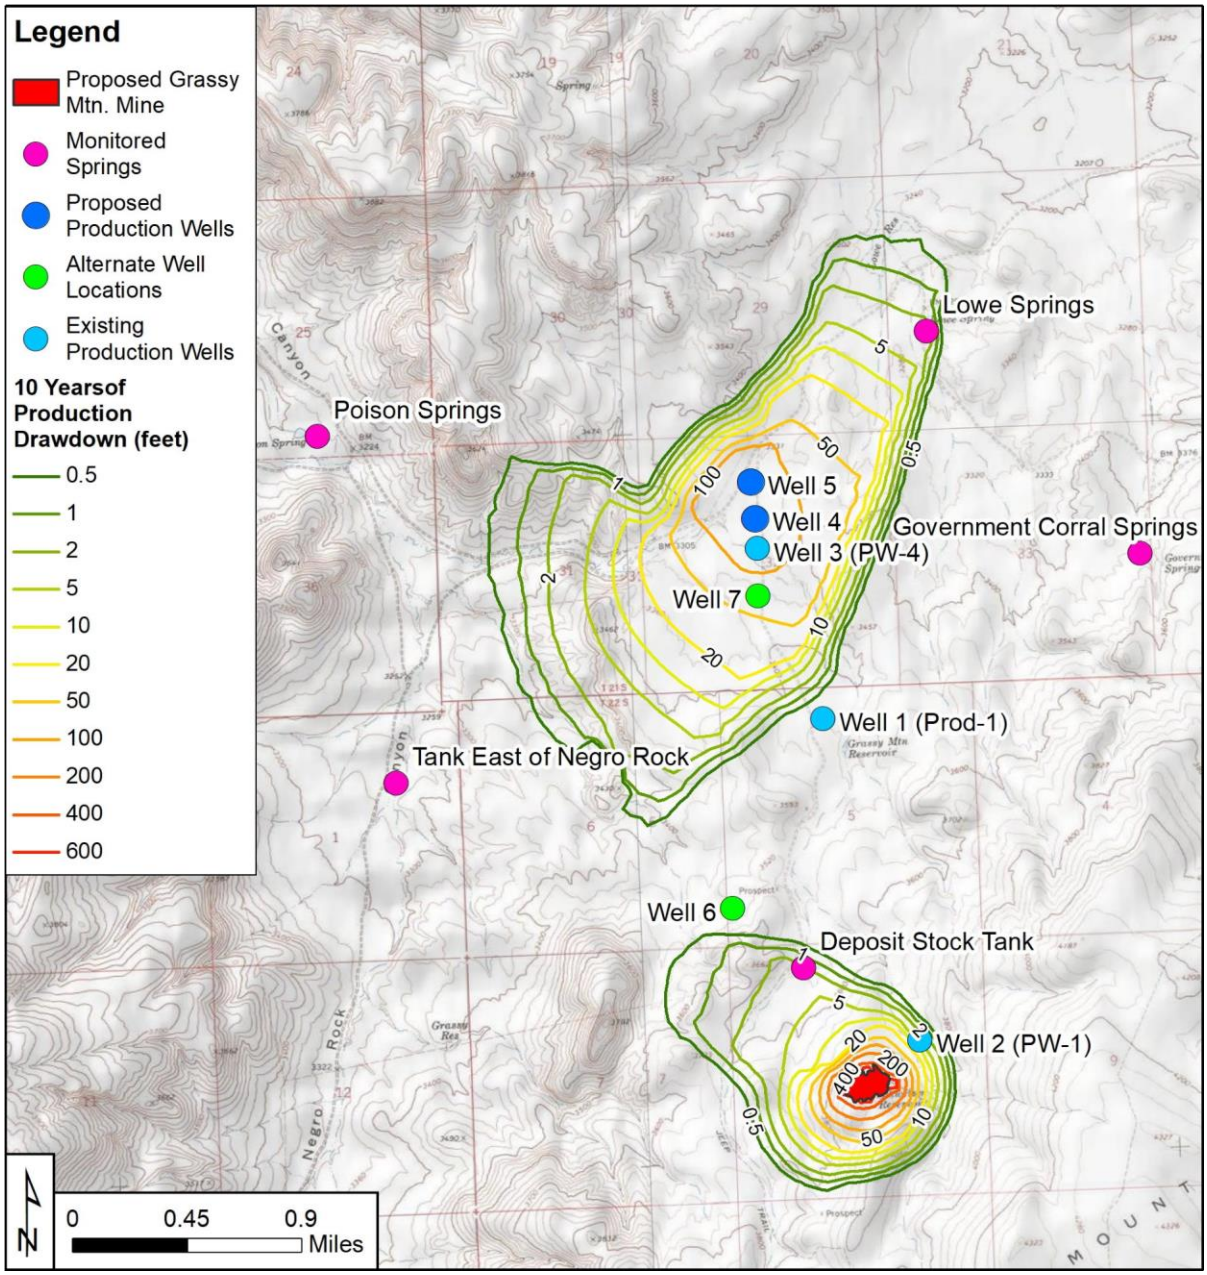

Figure 16. Drawdown after ten years of dewatering and production well pumping

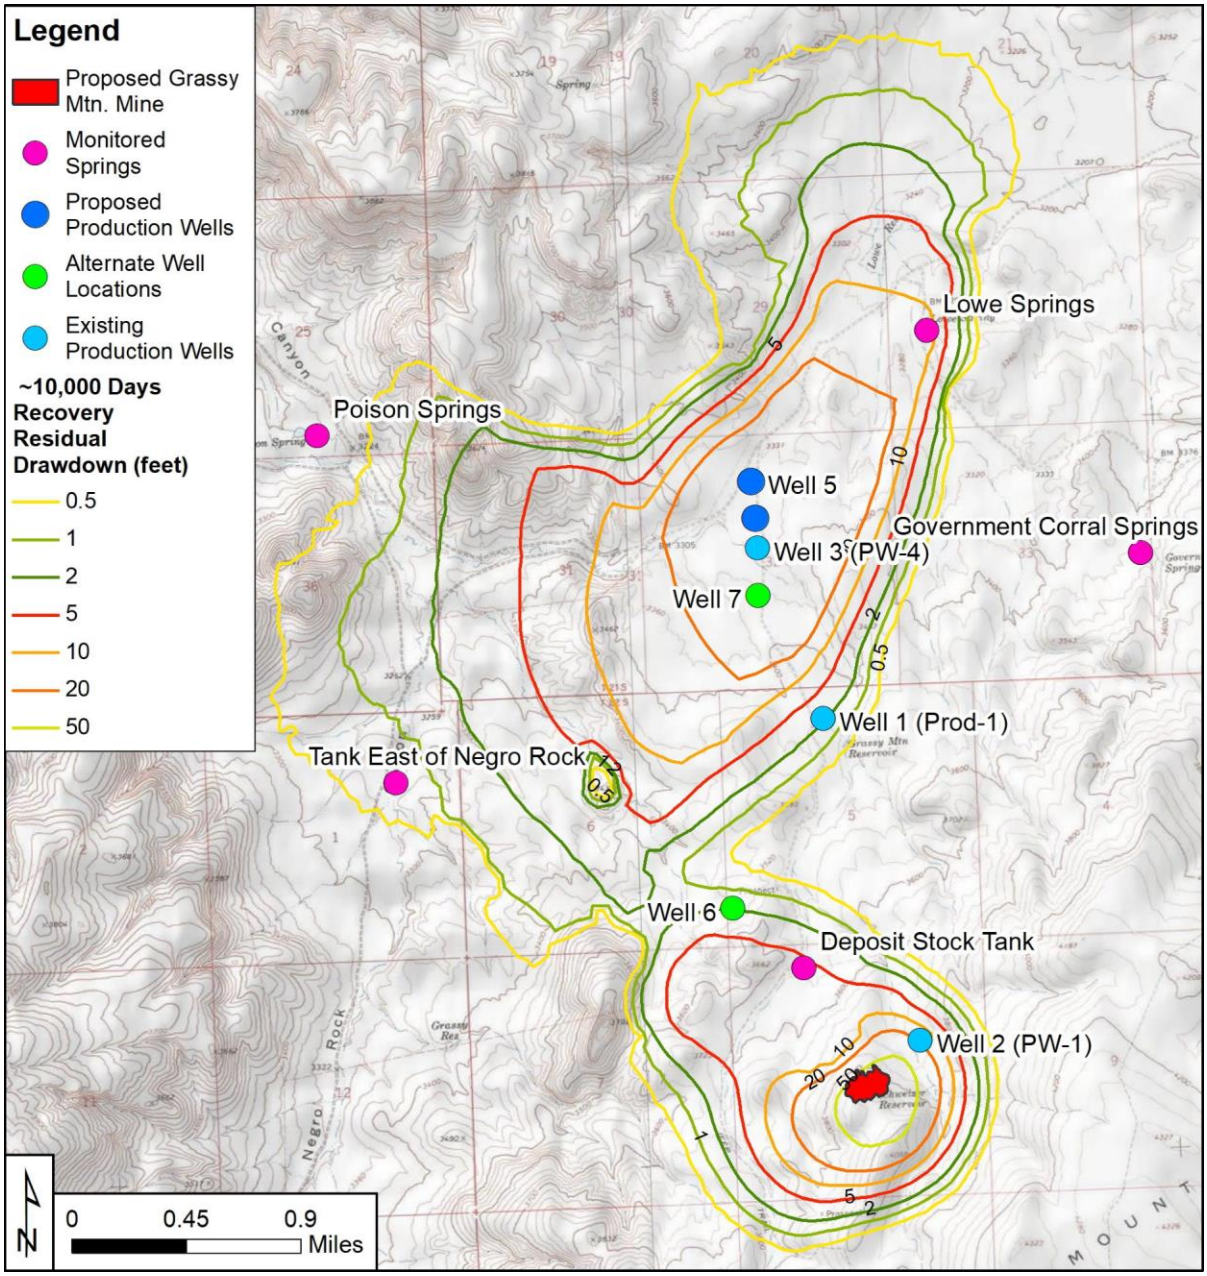

Figure 17. Residual drawdown after approximately 10,000 days of recovery

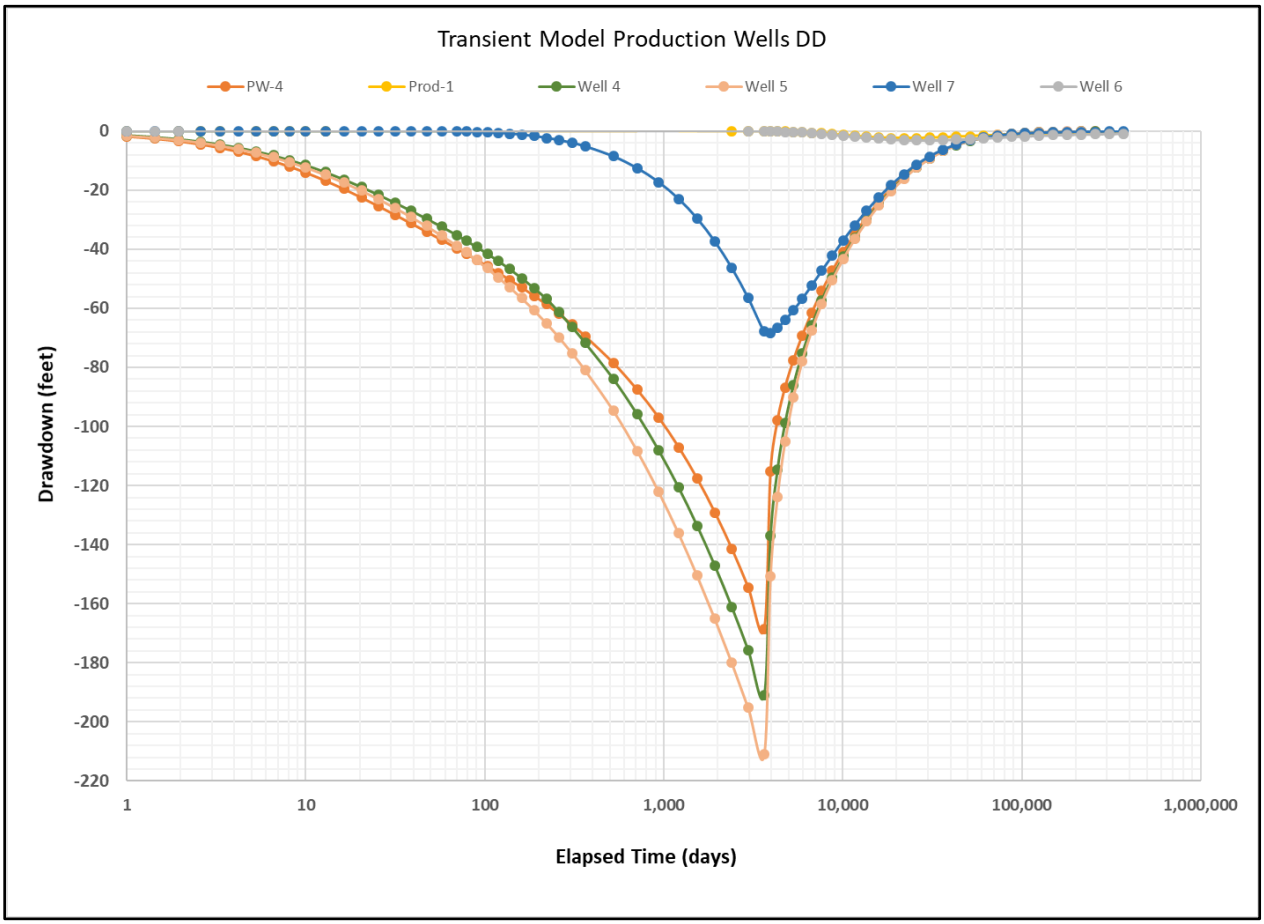

Figure 18. Transient model production wells drawdown prediction

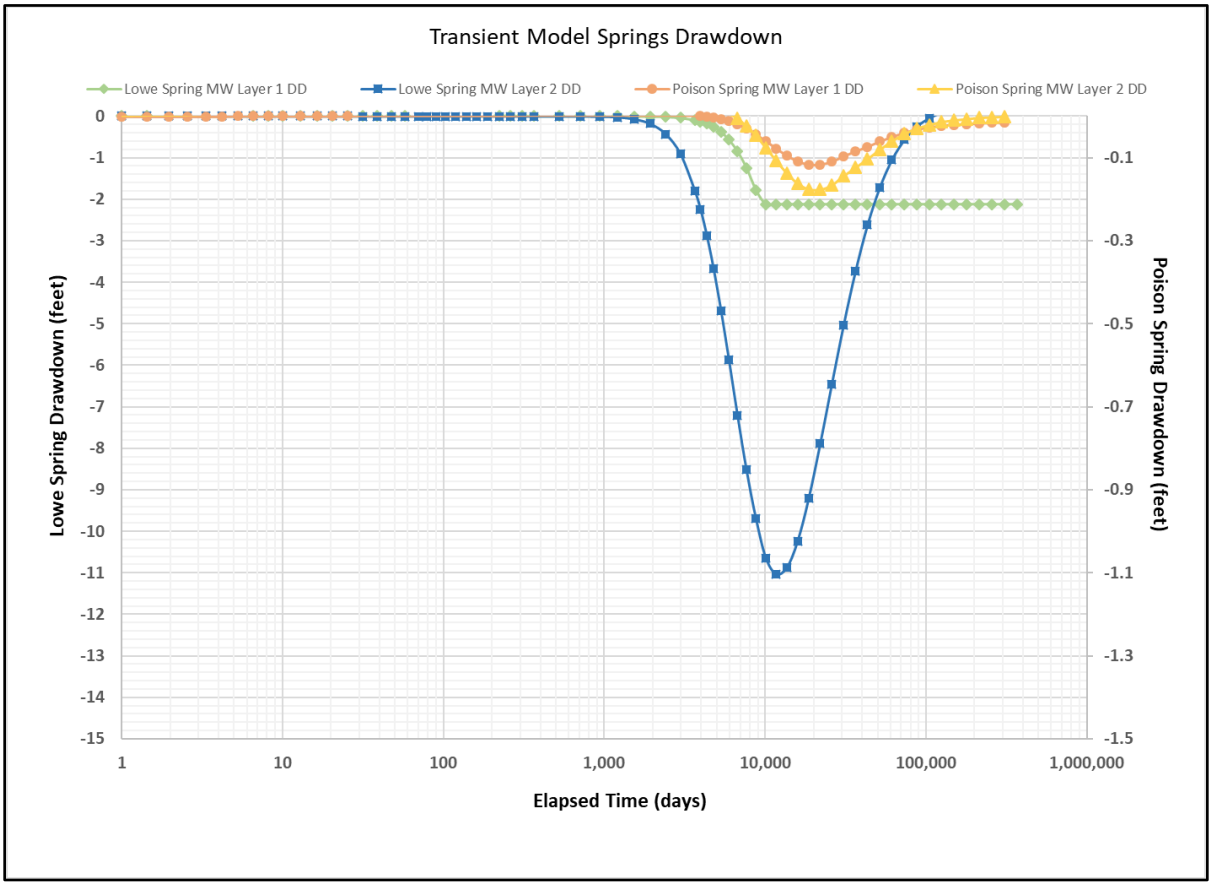

Figure 19. Transient Model Springs Drawdown Prediction

5.9.2. Other Factors Affecting Aquifer Drawdown

A transient model was used to predict aquifer drawdown and associated impact to springs. However, there are other factors to consider when attempting to predict impacts to springs, including source water characteristics (i.e. geochemistry), geology, and elevation differences.

A piper diagram, which includes the sampled wells and springs near the proposed production well area, is presented below as Figure 20. Due to the geochemical signature of Lowe Spring (more Ca-HCO3) being different from PW-4 (Na/K-HCO3), and because the location of Lowe Spring is near the contact between the different geological units (SPF 2021c), it is anticipated there may be less hydraulic connection between the production wells and the source of Lowe Spring; therefore, the modeled drawdown is probably conservative. Using similar reasoning, Poison Spring is more likely to be affected by the production well pumping because Poison Spring has a similar geochemical signature as PW-4; thus the model might under predicts impacts to Poison Spring.

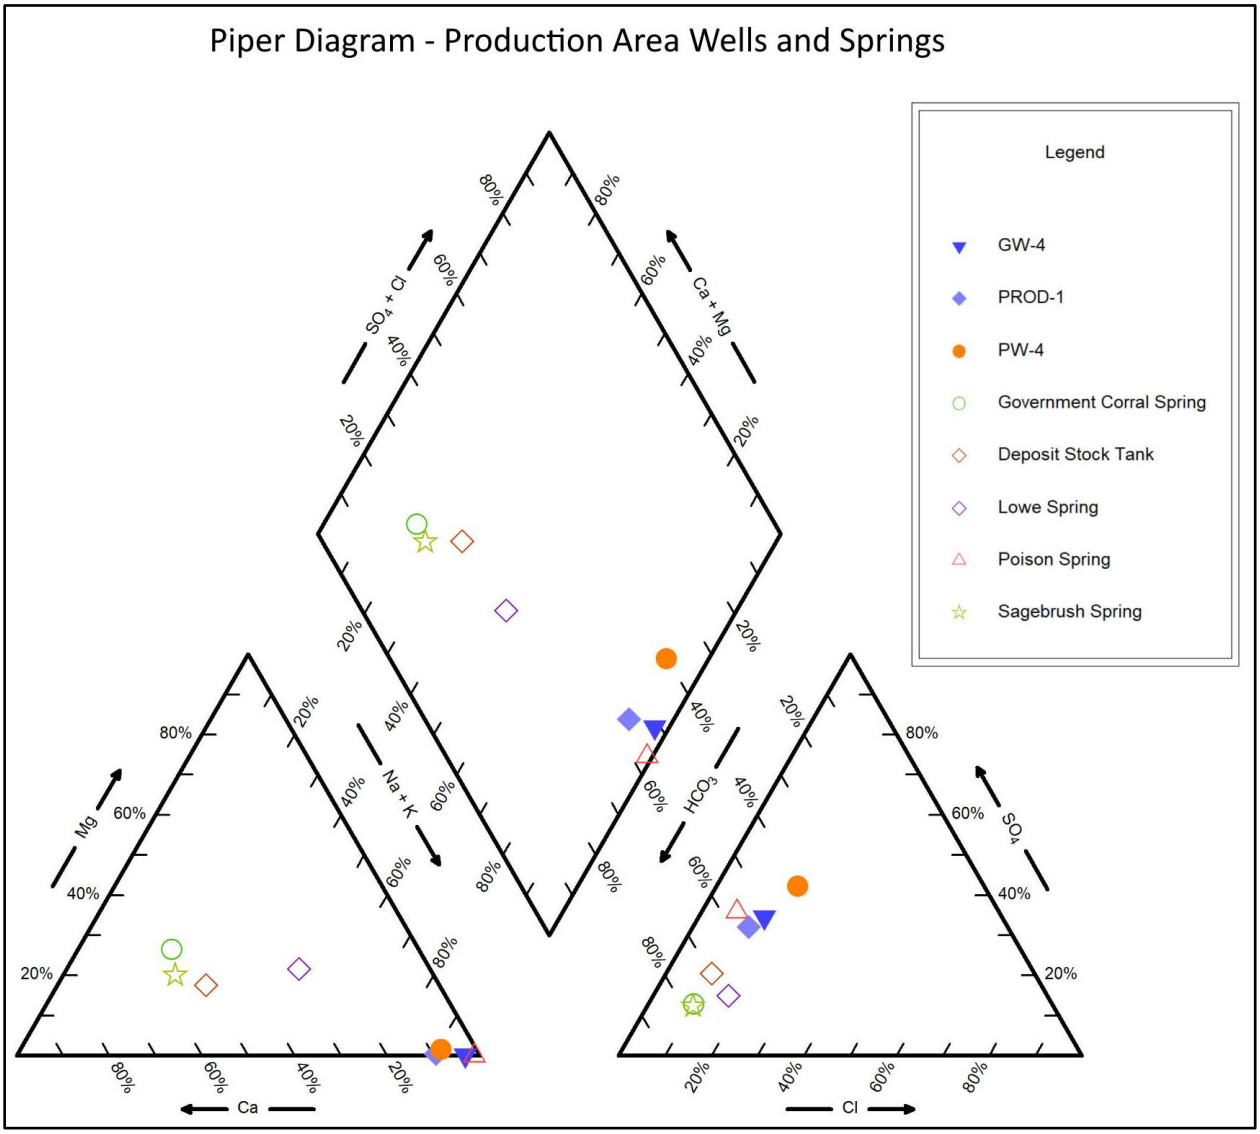

Figure 20. Piper Diagram Including Production Area Wells and Springs

Poison Spring and Lowe Spring are both presumed to be downgradient of PW-4. The water level elevation in PW-4 is approximately 3,261 feet amsl, while the elevation of Poison Spring is 3,213 and Lowe Spring is at 3,279. Lowe Spring, although located down gradient of PW-4, has a higher elevation than the water level in PW-4 further supporting that Lowe Spring has a different source than PW-4. The elevation of Poison Spring is consistent with its location downgradient of PW-4, suggesting a higher likelihood of a connection.

6. RESULTS AND CONCLUSIONS

The following points summarize the results and conclusions from this investigation:

1. The conceptual model for groundwater flow at Grassy Mountain provides the basis for preliminary dewatering estimates. The current conceptual model suggests a single aquifer system as a function of scale, supported by the relatively uniform, shallow and deep potentiometric surface (on a regional scale) and correlation with groundwater elevation and depth. On a local scale, heterogeneity effects are apparent, attributed to local variations in hydraulic properties, facies changes, and/or the occurrence of faults/fault zones.

2. Preliminary estimated analytical steady-state bulk dewatering rates on the order of 20 gpm, with the potential to intercept up to 500 gpm on a short-duration basis (i.e., days to weeks), are anticipated based on the analytical approach.

    a. The low-end estimate reflects lower permeability in the range of $1x10^{-6}$ cm/s (or 0.003 ft/d) anticipated directly within the resource area. Due to the expression of individual faults or fault zones, the actual permeability varies spatially and overall may be more or less. SPF is not aware of direct testing of hydraulic conductivity or transmissivity based on aquifer pumping tests within the resource area to date to confirm this estimate. However, the results of pumping tests performed around the perimeter of the resource extent support an aggregate lower hydraulic conductivity within this magnitude due to limited yields and negative boundary conditions.

    b. The high-end estimate reflects higher hydraulic conductivity that may be more representative of basin conditions (i.e., unconsolidated and consolidated sedimentary deposits) and short-duration inflows into the resource area (i.e., faults and fractures serving as conduits for flow) that could potentially be intercepted during the mining activities. The anticipated hydraulic conductivity may be on the order of $1x10^{-4}$ cm/s (0.3 ft/d). This condition may arise from contributions from local zones of higher permeability that are effectively dewatered in early time. As the cone of depression or radius of influence extends from the theoretical pumping well(s) with time, the overall aquifer properties are expected to produce less water due to overall lower permeability effects.

3. The dewatering evaluation also examined potential groundwater inflow rates using transient analytical methods.

a. The transient analytical (Theis) method was used to estimate the predicted dewatering rate of approximately 250 gpm to 600 gpm, assuming a single pumping well scenario, placed at the center of the proposed Grassy Mountain Mine. Note that these values greatly exceed the estimated recharge rate for the immediate vicinity of the mine.
b. The theoretical drawdown effects at the perimeter of the proposed Grassy Mountain Mine were evaluated after one year of continuous pumping to produce 600 feet of drawdown (assuming an initial groundwater elevation of 3,700 feet for upgradient conditions and an assumed dewatering elevation of 3,100 feet). The higher flow rate range is consistent with anticipated short-duration inflow amounts over the span of days to weeks.

4. A three-dimensional numerical groundwater flow model was developed and executed using MODFLOW to evaluate potential dewatering rates under steady-state and transient conditions.

    a. The model was constructed at a 10 mile x 10 mile resolution, centered on the proposed Grassy Mountain Mine, with three layers. Regional and local groundwater flow conditions were simulated based on a distribution of hydraulic conductivity and storativity (informed by geologic mapping and the results of aquifer pumping tests), recharge from surface infiltration predominantly in higher elevation regions, and assignment of boundary conditions to reflect physical boundaries to the extent possible (including Owyhee Reservoir, Owyhee River, and select spring features).

    b. The steady state model dewatering was simulated by placing wells along the proposed Grassy Mountain Mine perimeter and assigning uniform pumping rates to achieve dewatering to the 3,100-foot elevation. Four wells were simulated at 5 gpm each for 20 gpm total pumping requirements under steady-state conditions, resulting in a pumping level elevation of approximately 2,950 feet to 3,100 feet.

    c. The transient model dewatering was simulated by placing four wells around the perimeter and one well in the center of the proposed Grassy Mountain Mine and pumping a total 480 gpm for 70 days and 57.5 gpm for the remaining lifetime of the mine (approximately 10 years). The higher rate pumping for 70 days was able to lower water level elevations to less than 3,050 feet and the lower rate pumping initially allowed minor recovery then lowered the water levels to a range of elevations from 2,700 to 2,870 feet.

    d. The three-dimensional numerical model was created as a regional model for a baseline analysis of dewatering requirements. This model was

calibrated using the regional water levels. The deeper water levels located near the proposed mine and other highly silicified and compartmentalized areas are not represented in the model. The conceptual model report (SPF 2021b) discusses these deeper water levels and potential causes. Currently, there are no wells or piezometers completed in the highly silicified region encompassing the deposit area that have a static water level higher than 3,200 feet amsl. Drillers have indicated flows of up to 10 gpm in only 3 of the exploratory bores drilled in the proposed mine at depths shallower than 3,200 feet amsl. Only two of the exploratory bores in the proposed mine had a reported static water level shallower than 3,200 feet amsl. Due to its silicified and compartmentalized nature, the amount of water that flows through the proposed mine area is limited. The three-dimensional numerical dewatering model does not account for this limitation and should be used as a worst case estimate for the maximum flow that would be required to dewater the proposed mine in its entirety.

e. The planned mining method is drift-and-fill. This method used in the compartmentalized aquifer located at the proposed Grassy Mountain Mine will decrease the total volume of material requiring dewatering.

5. The transient model was also used to evaluate the drawdown effects of the dewatering wells and the mine operation production wells on the aquifer and nearby springs. Lowe Spring is approximately 1 mile away from the nearest proposed pumping well (Well 5) and had a predicted maximum drawdown of approximately 12 feet. Approximately 1.75 miles away, Poison Spring has a maximum predicted drawdown less 0.5 feet. The water sampled from Poison Spring has a similar geochemical characteristic as PW-4, while Lowe Spring shows a more volcanic geochemical signature. The geochemical signatures indicated Poison Spring may be affected by the groundwater production more than modeled and Lowe Spring may be affected less than modeled.

6. The dewatering and drawdown estimates reflect inherent uncertainty, both in the available datasets and necessary simplifying assumptions for representing a complex system. Therefore, these results are considered appropriate for baseline-level planning.

7. The accuracy of representing predominant groundwater flow paths and estimates of potential groundwater inflow depends on the sufficiency and accuracy of supporting data and assumptions. This process is inherently uncertain with respect to the conceptual model, translation of the conceptual to analytical and numerical models, and interpretation of results. Simplifying assumptions are necessary throughout this process.

The level of accuracy is considered appropriate for a preliminary baseline estimate. Overall, the magnitude of dewatering estimates generated during this investigation on the order of 20 to 100 gpm for long-duration pumping, and up to 500 gpm for shorter-duration pumping (days to weeks) are within the range of previous investigations that used different methods.

7. SUPPLEMENTAL REPORT

In March of 2020, Lorax Environmental Services Ltd. submitted a report on mine dewatering in support of the Grassy Mountain Gold and Silver Project Feasibility Study (Lorax Environmental 2020). Mine dewatering was estimated by using the same numerical model parameters as the model presented in this report, but with updates as follows:

- Utilized a finite element groundwater flow model with six layers
- Incorporated more detailed mine plans
- Established hydraulic conductivity values in the three-dimensional model space using 2019 resistivity survey data; calibration included using 2019 packer test data
- Included a structural feature (may be construed as a fault acting as a flow conduit) that resulted in more reliable model calibration

With these updates, the groundwater inflow rates were predicted to range from 12 gpm to 78 gpm, which is consistent with the long-term flow rates (after initial dewatering) estimated by this report (57 gpm). The updated dewatering assessment is included Appendix E.

Assumptions
Assumptions inherent to the use of the non-equilibrium well equation (Theis, 1935) are that the aquifer is homogeneous and isotropic, uniform in thickness and areal extent, the aquifer receives no recharge, the pumping well penetrates the full aquifer thickness, water removed by discharge is removed instantaneously, the pumping well is 100 percent efficient, laminar flow exists throughout the aquifer, and that the water table or potentiometric surface has no slope. These assumptions are rarely completely satisfied under field conditions, but this method will often provide an indication of possible well interference.

Assumptions
Assumptions inherent to the use of the non-equilibrium well equation (Theis, 1935) are that the aquifer is homogeneous and isotropic, uniform in thickness and areal extent, the aquifer receives no recharge, the pumping well penetrates the full aquifer thickness, water removed by discharge is removed instantaneously, the pumping well is 100 percent efficient, laminar flow exists throughout the aquifer, and that the water table or potentiometric surface has no slope. These assumptions are rarely completely satisfied under field conditions, but this method will often provide an indication of possible well interference.

Assumptions
Assumptions inherent to the use of the non-equilibrium well equation (Theis, 1935) are that the aquifer is homogeneous and isotropic, uniform in thickness and areal extent, the aquifer receives no recharge, the pumping well penetrates the full aquifer thickness, water removed by discharge is removed instantaneously, the pumping well is 100 percent efficient, laminar flow exists throughout the aquifer, and that the water table or potentiometric surface has no slope. These assumptions are rarely completely satisfied under field conditions, but this method will often provide an indication of possible well interference.

Assumptions
Assumptions inherent to the use of the non-equilibrium well equation (Theis, 1935) are that the aquifer is homogeneous and isotropic, uniform in thickness and areal extent, the aquifer receives no recharge, the pumping well penetrates the full aquifer thickness, water removed by discharge is removed instantaneously, the pumping well is 100 percent efficient, laminar flow exists throughout the aquifer, and that the water table or potentiometric surface has no slope. These assumptions are rarely completely satisfied under field conditions, but this method will often provide an indication of possible well interference.

Assumptions
Assumptions inherent to the use of the non-equilibrium well equation (Theis, 1935) are that the aquifer is homogeneous and isotropic, uniform in thickness and areal extent, the aquifer receives no recharge, the pumping well penetrates the full aquifer thickness, water removed by discharge is removed instantaneously, the pumping well is 100 percent efficient, laminar flow exists throughout the aquifer, and that the water table or potentiometric surface has no slope. These assumptions are rarely completely satisfied under field conditions, but this method will often provide an indication of possible well interference.

Assumptions
Assumptions inherent to the use of the non-equilibrium well equation (Theis, 1935) are that the aquifer is homogeneous and isotropic, uniform in thickness and areal extent, the aquifer receives no recharge, the pumping well penetrates the full aquifer thickness, water removed by discharge is removed instantaneously, the pumping well is 100 percent efficient, laminar flow exists throughout the aquifer, and that the water table or potentiometric surface has no slope. These assumptions are rarely completely satisfied under field conditions, but this method will often provide an indication of possible well interference.
